efforts to devise an apparatus for making distinctions, the importance of which he had so forcibly urged. He had put very clearly the advantages of flashing lights, by reference to the dynamic law that what was gained in power was lost in speed, which was strictly true. But, optically, the light you did not get when you did not see it, you did get concentrated in one flash when you did see it. With an ordinary light, giving a single flash of four seconds, with a period of half a minute, you got seven and a-half times as much light in that flash as you would with a fixed light burning the same quantity of oil. That advantage was very great, and could not even be made up by burning seven and a-half times as much oil, because, if you did that, you would have a larger source of light to deal with, which would throw greater difficulties in the way of the optical engineer. The greatest part of the diminution of light at a distance was due to absorption by the air, which was a larger cause of limitation than that due to the diffusion over a greater area, in proportion to the distance, so that if the weather were at all thick, the light might be reduced to 1-10th, 1-30th, or even 1-100th for every mile of distance, so that if you increased the power seven or eight times, you would not increase its range in the same ratio, particularly in thick weather. For all that, it was of vital importance to push the lights as far as was possible. With regard to the Royal Sovereign and Casquete, they were of a totally different character, so far as optical arrangements were concerned, the former being a floating light with catoptric apparatus, a series of reflectors with a flame in the focus of each, and with the construction of that light he had nothing to do. The Casquete was a dioptric light with a single flame in the focus. Sir William Thomson had urged that these large dioptric lights would be greatly improved if the revolutions were made much quicker, and he quite agreed with him, but in the case of the Casquete experiments had been carefully tried, at 16 seconds and 30 seconds, and he believed the opinion of those most experienced was that the half-minute light was the better. There was, however, a great difficulty in running these heavy lights at the speed suggested, not from any difficulty in making machinery strong enough to stand the wear and tear, but in getting the motive-power, that could be only obtained from the ankers of the light-keepers, and his opinion was that at the Casquete those ankers were already taxed somewhat severely. Indeed, if ever a light-keeper were inclined to strike it would be at being called upon to make these heavy three-ton apparatus revolve at a velocity which would give a triple flash every ten seconds. At the Bull Point, the labour had been somewhat reduced by improving the machinery. With regard to eclipsing lights, he did not think there would be any difficulty in having a reasonably rapid group of flashes, either with Sir William Thomson's machine, or with the one which had been for some little time in use in English lighthouses, and which had lately been introduced in China. There were first and second order lights, and the eclipsing screen, which was made of sheet iron, rose and fell something like two feet in some cases as rapidly as in half a second, which speed was quite sufficient to meet any ordinary requirements.

Captain Sir George Nares, K.C.B., F.R.S., said if men had not the "three F's," they had "three L's." Sir William Thomson had helped them to improve each. They were, the lead, the log, and the look-out. He had improved the lead, he had improved the log by improving the compass, and now he was trying his utmost to improve the lights and so help the look-out. But with these numerous distinctions they would have to educate the seamen, even the intelligent captain and his mate, to understand them. The Board of Trade were advancing very fast in the matter of examinations, and Sir William Thomson would do a great deal of good

if he could induce the officials of the examining captains and mates in these matters they had not the slightest idea of any distinction between a flashing and an eclipsing light, they both revolving. Sir William Thomson, letter S, and they were ready to accept single, double, or triple flash, or even four, he did not think he was yet sufficient; he saw two lights, one on each side, short and long, and the other long and single, which was which.

Thomson was working in the right direction, they did not want to go too far. They wanted distinct characters of light on the coast to be enough. Before going further to be well educated up to what they had.

Captain Ladd (of the Trinity House) said he forgot that a floating revolving light times the penetrating power of an occult flash light, and Mr. Hopkinson's light, explained, had seven times the power. In this he agreed with Sir George Nares.

Dr. Gladstone, F.R.S., desired to echo what had been said as to the importance of many years ago it occurred to him that on important improvements in this matter distinction between lights, every lighthouse readily distinguished from lights on the lights, and so on, and to be distinct from hours. Before coming to the meeting, he to the report of the Royal Commission, of which he was a member, per and there he found it was laid down that should be placed on any important position, the reason being the evident were apt to be confounded with ships' lights other lights on shore. There was also in a revolving light, as had been explained was gathered up and concentrated, so that much greater distance. Last summer, from Swansea to Ilfracombe, he had met the Bull Point light arrayed with son's apparatus, there was a distinction could see at once, the two short flashes interval of darkness following them, and some days he watched it with great interest had the pleasure of examining the apparatus into the report which he had mentioned, he had entirely forgotten, that a gentle recently become notorious in another Felham Dale, brought before the Commission for the distinction of lights identical with that now advocated by Sir William. He suggested that lights should be than ten distinctions, that they should be Roman numerals by occultations; that a light should represent the I, and a light should represent the IV, and another to represent the V. He also drew out a scheme for marking lighthouses in a similar way by daylight flags, and by suitable sounds in fog. There ought certainly to be carried out all round and a very few would suffice. He did go with Sir William Thomson in what he preferred for occulting lights over revolving lights appeared to him that the former had two. One was, that during the obscuration you amount of light, which was not sufficient in a revolving light, and, secondly, you have such a penetrating light. There was the argument, that what was lost in one gained in another, but it seemed to him the most points on the coast it was advisable revolving light like that on the Casquete which should be more rapid in action than

other places, where it was not necessary that should carry so far, the occulting light might with advantage.

Gibbs said he remembered the two terrible which occurred 40 or 50 years ago between and Cape Grinez, of the *Reliance* and *Meru*, involving an immense loss of life, were caused by these ships mistaking the light for Dungeness. From that time, the of both countries had done their best to the lights so distinct that such an accident occur again; but yet, during the last winter, had been wrecked near Boulogne from the same. It was all very well to watch the experiment that room, but it was a very different thing to in the flashes on a dark winter's night in a. He for one, did not think they would be dis- by the most intelligent captain in the Royal the captain of the finest steamer. The cap- collars did not care about them; they took to pass any light until they knew what it was. truly was with the captains of fruit schooners from the Azores, racing up to London with a he wanted to know what light it was they first in the English Channel, when perhaps they quite correct either in their latitude or longitude. had hail with satisfaction any practical plan enable the sailor to do so, but he thought the stem was far superior to the one now proposed. I from a description by Mr. Brassey, of his the Bay of Biscay, with a fine ship and a w, to show that it was possible to mistake a thead light for a green light; and he had then found it impossible, on coming into the hannel, to see any light at all. In summer fine weather he could distinguish perfectly ghts on the Goodwins from his window, at but in winter time, very often he could not t all.

H. Procece said if he had been imprudent in cees, as Sir William Thomson suggested, how e imprudent had he been himself, who was o suggest to him at the meeting of the ociation at Brighton, that the proper system ouses was to adopt the Morse alphabet. e the dream of a telegraphist, but he who nearly all his life reading signals by ashes, high notes and low notes, and other the kind, would not have the slightest a reading off by these flashes of gas-light a livered by Sir William Thomson, and he vard to the day when the lighthouses round ould shout out not in audible, but in visible to every nation on earth its name and If it was a dream, it was certainly within the practical engineering, and gradually, but Trinity Board, and the Board of Trade, were he necessary education, in which they were helped by the persistent efforts of reformers illiam Thomson. But whilst they were being p to the Morse alphabet, Sir William Thomson e running away from it, so as, in many other ght be said that extremes met, and so it would they had their lights established on a principle o ran might read. A flashing system no d counting, than the words Trinity House ling. If those words were written up in cters, the whole group would convey the idea House at one glance; and so, whether you e Morse alphabet, or the flashing system, or ig system, if you simply applied a system he eye was enabled to grasp at one view the ame of the lights, you attained exactly the as if you printed the word. That was the Sir William Thomson was advocating, and would continue writing papers and pressing

forward the subject until the Trinity House adopted a sensible system.

Dr. C. W. Siemens, F.R.S., said the subject was one of great interest to him, but he had not given sufficient attention to the details to be able to speak with any authority upon it. He might say a word or two, however, on the probability of seeing the electric light established for the purpose of giving those flashes which had been referred to. He might certainly say that the electric light appeared destined to take the place of all other lights for that purpose. In dealing with light produced by the combustion of oil or gas, they were necessarily limited to the amount to be obtained under given conditions. A large amount of light could be obtained by combustion, but it could not be concentrated within the focus of a lamp. It was only by the electric current that small surfaces could be heated to a point far exceeding the temperature attainable by combustion, and send out rays of light second in energy only to those of the sun. It had been proved by St. Clair Deville, and Bunsen, that the utmost temperature to be obtained by combustion was about 2,400°, when a point was reached at which combustion ceased and dissociation set in; and therefore it was impossible to obtain rays of high intensity by means of combustion. There were, no doubt, practical difficulties to be overcome in applying the electric light to some situations where power could not be easily raised; but means of producing power were continually being improved. Where you could not raise steam you could decompose oil; and where you could not work a steam-engine you could a gas-engine or an oil-engine, as was already done in the United States to a large extent. With the electric light also an admirable system of flashes of any desired rapidity could be attained; and he would conclude by expressing a hope that they would soon attain the desired point when each lighthouse would not only tell its own tale, but also give that information to the greatest possible distance.

The Chairman said it must be borne in mind that, in listening to this paper, they were not listening to a mere scientific man, unacquainted with the practical details of seamanship, for there was no more ardent yachtsman than Sir William Thomson in all England; and they would all remember the way in which he indignantly repudiated the idea that the man who, in the midst of storm and tempest, could navigate a vessel along the shores of England, from Newcastle to London, with a cargo of coals, was not a man of intelligence, or that he could not do as much it was said a crow could do, viz., count four. Sir William Thomson had already given to navigation a sounding implement and a compass, now very largely used, and he was the apostle of this doctrine of the identification of lighthouses, the necessity for which was so apparent that it was not necessary to take up time by dwelling upon it. It was better to be without a light at all, than to have one which was misleading; and it was to prevent this misleading, which became more and more likely every day, having regard to the fact that a white light, in a lighthouse at a distance, could readily be mistaken for another white light in the immediate neighbourhood, that this system was devised. Sir William Thomson, by his persistence in this matter, was doing infinite good, and was likely to save many lives which were now lost in consequence of the mistakes made in distinguishing one light from another. A supposed quotation from the Bible had been made more than once, and, as usual, it was misquoted. They had been told of a light, "which he who runs may read," whereas it should be "that he may run who readeth;" in other words, that what was read should be of such a terrible character, that he who saw it ran away from it. Sir William Thomson, in reply, said he would first

read an extract from a letter which had been put into his hands since the discussion commenced. It was from Mr. J. R. Wigham, of Dublin, one of the great improvers in gas appliances for lighthouse purposes; and he said:—"Knowing a little of the efforts which are being made by the Irish Lights Board and their scientific adviser, Dr. Tyndall, in the direction of the plan you advocate, I thought I would mention that they have at last obtained the consent of the Board of Trade, to fix a group flashing gas-light at Copeland Island." With regard to Dr. Hopkinson's statement as to the possibility of giving the rapidity he desired to a triple-grouped flashing light, he could only say that the difficulty he had mentioned was no doubt real, and he did not wish to have anything very extravagant attempted; if it were to be a severe tax on the light-keeper to make the Casquets light much quicker, he should prefer leaving it as it was. He only wished to keep rapidity in view, in all cases in which it can be attained; and although it was said that double speed was not so good as that adopted, it did not follow that that quadruple speed would not be much better. They might look forward to much greater speed with the electric light, with its extreme pliability in respect of stopping and starting. The electric light on the tower of Glasgow University, during the exhibition of gas and electricity, in October last, constructed by Messrs. Latimer Clarke and Muirhead, gave identifying occultations, long and short, in the most admirably perfect manner, by extemporised mechanism, and worked with all the quickness desired. Sir George Nares spoke of 70 distinctions of lights, but what he had brought forward was a plan for simplification. Instead of 70 distinctions of an unsystematic character, he proposed to have only two classes, flashing and occulting, each divided into nine varieties. He certainly should not like to have to distinguish between a long and short on his right hand, and a short and long on his left, but wherever there were two lights near each other, on the two sides of a channel for instance, the difference should be made as marked as possible. The Chairman had used an admirable expression in speaking of the identification of lights; that was what he wanted, that each light should identify itself. He did not approve of either numbers or letters being associated with the signals, but preferred long-short, long-short-short, and so on; still more did he object to anything like spelling names, which he had been most mistakenly accused of recommending. He had even been accused by a scientific expert, in a lecture, of having proposed to the Clyde Navigation to spell out C.U.M.B.R.A.E., though in the very building in which the lecture was given he had specimens of lights giving identifying signals such as he described. With regard to the question of the flashing and fixed light, as stated by Dr. Gladstone, he preferred the fixed light, and the character given by the occultations for the reasons he had stated, but he had endeavoured to weigh, as fairly as possible, the respective advantages, on the one hand of never losing sight of the light, and on the other the greater brilliancy. Dr. Hopkinson had pointed out why, even by increasing the consumption of oil, the fixed light could not reach the brilliancy of the flashing light, except by gigantic optical appliances; but even assuming all new lights were of the flashing order, there were 490 fixed lights, and what was to be done with them? The experience of Mr. Brassey, as quoted by Mr. Liggins, proved conclusively that a white light might be mistaken for a green one, which showed how necessary it was to have some better means of identification. Lastly, he wished to say that he had not quoted from the Bible at all, but from the Trinity Brethren.

The Chairman then proposed a cordial vote of thanks to Sir William Thomson, which was carried unanimously, and the proceedings terminated.

## MISCELLANEOUS.

### SILK-PRODUCING BOMBYCES REARED

By Alfred Wailly

(Membre-Lauréat de la Société d'Acclimatation de l')

(Continued from page 285.)

*Telea Polyphemus* (North America).—This which produces a closed cocoon, a little smaller than that of *Pernyi*, is the best of the silk produce United States of America. The silk is white, and seems to be of a very superior quality, easily be bred like *Pernyi* in the open air, in unless the weather should be exceptionally bad. *polyphemus* is now acclimatised in Spain, where I reared it in 1879. In 1880, some 1,500 wild cocoons collected from oak, birch, and other trees. It is polyphagous. My Spanish correspondent reared *Polyphemus* as a valuable acquisition to sericulture in Spain, but he says it has a tendency to double-brooded there, two male moths having emerged in November. The larvae thrived well on birch (*alba*). My correspondent in Alabama, from whom I have just received some *Polyphemus* which are very small, and covered with the scales of ever-green oak, says it is double-brooded in Alabama, as it must be in all the Southern States of America; in the Northern States it is single-brooded.

*Samia Gloveri*.—In 1880, I received a large quantity of cocoons of this North American bombyx. I collected, my correspondent wrote to me, some south of Salt Lake City, Utah, in a locality never before previously explored. As far as I am informed, this fine species, up to the present, has been found in Utah and Arizona. The cocoons collected in plantations of a species of willow with small narrow leaves. The cocoon, somewhat smaller than that of *Samia cecropia*, is greenish silvery grey outside; the rough envelope and the cocoon inside, which is of a very dark brown. *Gloveri* moths emerged from the middle of April to the middle of July, but no pairings could be obtained.

*Samia Ceanothi*.—This species, a little smaller than *Gloveri*, is a native of California. The moths vary in shades of colours like *Cecropia* and *Gloveri*; the ground colour of the wings is of an uniform brown; the bands and markings are pure white. It partakes of *Ceanothi* and *Cecropia*, as if it were between these two species.

The cocoon of *Ceanothi* is very different from *Gloveri* or *Cecropia*; it has the open end very small and is pear-shaped; its colour is iron-grey. The cocoon is brown, and small, compared to that of *Gloveri*.

The moths of *Ceanothi* (of which I had reared many cocoons) emerged from the 3rd of April to the 10th of July; a perfect specimen had emerged in May. Pairings only were obtained. The larvae bred on willow did not thrive, and died in first and second stage, a few going into third stage. From a letter received from one of my German correspondents, Mr. Wolff, of Breslau, I hear that three cocoons obtained by this entomologist with only six days to the disposal, a very great success, considering that he has attended the efforts of several others in the same way.

The first pairing of the *Ceanothi* moths took place the 27th of June, the second on the 10th of July. The ova of the first brood hatched 18 days, and the second, 15 days after having been deposited.

The larvae, somewhat similar to those of the first and second stage, but of a light green colour, showed a marked difference in the third stage.

thus:—Back of body, sky-blue; sides, greenish  
v; tubercles, golden yellow all along the back, and  
sides, blue; head green.

*birds*.—Although *Samia gloveri* moths refused to  
among themselves, I had several crossings between  
*ri*, *Ceanothi*, and *Cecropia*. The ova obtained from  
pairing between a *Ceanothi* female and a *Gloveri*  
were the only ones which were fertile. Unfortun-  
ly the larvæ, reared on willow and plum, all died,  
stretching, like *Ceanothi*, the third stage. The pair-  
of *Ceanothi* and *Gloveri* was from the evening of the  
to the evening of the 21st of May. The larvæ  
from the 15th to the 21st of June, the majority  
hatched on the 16th and 17th of June. All the  
larvæ, excepting a few; over 200 in all. First  
larvæ, black; smaller ones, buff, the  
becoming of a more uniform hue as the larvæ  
in size. They were very much like *Cecropia*.

Second stage—Larvæ, yellow, with black  
head, black. Third stage—Back, bluish;  
yellow; tubercles on back, orange-red; tubercles  
blue; head, yellow.

Larvæ, the produce of a pairing of female  
*Gloveri* with unknown *Samia* (the pairing was not  
had seven days on plum; they were bright  
with a dark ring round each segment.

Other crossings resulting from the keeping of  
species together in large cages, when male and  
moths of the same species could not be obtained  
separately, are the following:—In a hot-house, at  
Bombay, on the 22nd of May, *Teles polyphemus*  
(male) with *Attacus mylitta* (female), of the Bombay race;  
*polyphemus* (female) with *Attacus pernyi* (male);  
*Gloveri* (female) with *Pernyi* (male). In my house,  
very temperature, on the 12th and 13th June,  
*Ceanothi* (female) and *S. cecropia* (male); on 15th  
*Gloveri* (female) with *S. cecropia* (male); on the  
19th June, *S. cecropia* (female) with *S. ceanothi*.

In all the above cases, the ova were unfertile.  
difficulties I have experienced to obtain living  
from India and other distant countries, induced  
October to write an article on the collecting and  
of larvæ, and on the best plan to be adopted for  
king of cocoons and pupæ, so that they should  
in England in good condition. This article was  
India, China, and South Africa. It appeared in  
*the China Herald*, of November 25th, 1880, and  
*Madras Athenæum* and *Daily News*, of Saturday,  
14th, 1880. It was sent also to correspondents  
in the *Times of India* (Bombay), the *Calcutta*  
*man's Overland Mail* and the *Cape Argus*.

As residing abroad, who may be willing to collect  
larvæ of *Lepidoptera*, will find this a most in-  
teresting and instructive study. It is within the reach of  
all at the same time profitable, as the pupæ and  
obtained would be purchased from them by other  
men. Larvæ can be found in almost unlimited  
numbers by using a sweeping-net over low plants, or  
low bushes, shrubs, and trees, placing an umbrella  
over the branches to receive them. Larvæ which hide  
themselves in the day time can only be found in large  
numbers by looking for them at night with a lantern.

Rearing of the caterpillars, after a little ex-  
perience, will be found extremely easy. Some will  
be placed in cages, when active and apt to  
crawl; others, like the silk producing Bombyces,  
are reared uncovered on branches plunged into  
water care being taken to use long branches (never  
wigs) when the larvæ are large. When very small  
larvæ are used, the foliage becomes too watery, and  
causes the death of the larvæ. Cut leaves have to  
be renewed too often, and therefore should be avoided,  
and the larvæ whenever cut branches plunged in  
water can be used. Branches should also be cut in the

evening or early in the morning, and not in the day-  
time when the sun is hot, as, in the latter case, the  
foliage would soon be faded. When trees in pots can  
be used to feed the larvæ, the rearing is, of course,  
more simple, and there is a saving of time. Another  
plan, which is the best to rear larvæ forming cocoons in  
the leaves or on the branches, is to place them on the  
living tree in the open air, taking care to protect them  
from birds.

To give fresh food to larvæ reared on cut branches  
kept in water, when the foliage has been eaten, or  
is too old and dry, is very easy. The old branches are  
merely placed in contact with fresh branches, or the old  
branches cut in pieces (not to be too heavy) are placed on  
the new ones. The larvæ, which should not be handled,  
will leave the old branches to go to the fresh ones. In  
a short time the old branches, bare of larvæ, may be  
removed.

When branches are plunged in a bottle, or any other  
vessel containing water, the foliage at the base of the  
branch should be cut off, as leaves in the water would  
decompose it, render the rest of the foliage unwholesome,  
and even poison the larvæ. The cut branches in water  
should be placed in the shade, where they will keep fresh  
for several days, especially if the foliage is sound and  
healthy, a condition of great importance. The water  
should be renewed, and the foliage freed of green flies  
and other small insects.

To rear *Lepidoptera* from the egg the moths should  
be placed in cages for pairing and depositing their eggs.  
With moths of *Sphingidæ* and some other species, it is  
useful to put in the cage a bunch of aromatic flowers,  
with branches of the plant the larvæ feed upon. Moisture  
should always be maintained in the cages.

A few days, or immediately after the eggs have been  
obtained, they should be placed under a glass with a  
small branch or leaves of the proper plants, so that the  
larvæ should find their food as soon as they are hatched.

When the larvæ are small, I rear them under bell-  
glasses, having a few holes on the dome. These glasses,  
which are of various sizes, according to the number of  
larvæ, rest on saucers full of sand covered with a piece  
of paper. Small branches of the proper food plants are  
struck through the paper and plunged into the sand,  
where they keep fresh for several days without requir-  
ing any water.

The larvæ, under a bell-glass, can be watched and  
kept perfectly clean, for, after having removed the  
glass, it is sufficient to blow on the paper to remove all  
the dejections. Some larvæ may thus be reared till they  
turn into pupa state, under glasses one foot high and  
one foot in diameter, or larger, according to the size of  
the larvæ. With larvæ of the large silk-producing and  
other Bombyces, after the first or second moult, when  
they have ceased to wander, it is best to rear these  
without the glass covering; branches plunged in water  
are then used, as mentioned before. The larvæ should  
be reared in the open air, but sufficiently protected, or  
in a well ventilated room. Larvæ which go into the  
ground to turn into the pupa state should be reared in  
cages containing a few inches of light soil or soft sand,  
and this plan must always be adopted when the habit of  
the larvæ is not known.

Now, with respect to the sending of living cocoons  
and pupæ from abroad, on the cases there should be  
written in large letters, "living pupæ," or "living  
cocoons of silkworms," with request to keep the cases  
in the coolest place, or in the ice-house of the vessel.  
The cocoons should be well packed in straw, hay, moss,  
or anything that will deaden the shocks to which the  
cases may be subjected. Pupæ of *lepidoptera* must be  
placed in bran, sawdust, or fine moss. Cocoons and  
pupæ should be sent as soon as possible after their  
formation, from the beginning of October to about  
the beginning of April, according to distance, so that  
they should not be subjected to the heat the whole of  
the time during their voyage to England. Small quan-

In a letter just received from Major G. Cousmaker, I hear  
an article appeared in the *Times of India*, and also in the  
*Agriculturalist*.

titles of cocoons and pupæ should be sent by sample post, in registered boxes, not exceeding the legal weight; the boxes must be strong, and it is best to tie a label to each box, and affix the stamps to the label. Persons living too far inland to send living pupæ may send dead specimens of the perfect insects (butterflies and moths). These should be in good condition, and placed with folded wings in paper envelopes. To protect these specimens from the attacks of mites, "Dermestes" beetles, and other parasites, it is important to put some poison in the boxes containing the specimens.

With respect to the sending of live cocoons and pupæ, and even ova of lepidoptera, I may say, that with a little care, and especially if they were given in charge of the captain, or some other person on board ship, they could be sent to Europe from distant countries, and arrive alive, and in good condition.

In proof of this, I may mention the fact, that Mr. Youl, acting as agent of the Tasmanian Government, shipped in 1864, packed in a box, which was placed in the ice-house of the steamer *Norfolk*, a large quantity of salmon and trout ova, the result being the successful introduction of salmon and trout into the rivers of Tasmania and Australia.

In the same way, silkworm ova, live cocoons, and pupæ could safely be sent to Europe, from very distant countries, and this would be of the greatest interest and value to entomologists, for the study of lepidoptera in their various states.

To conclude, I shall reproduce the letter of one of my correspondents, Mr. J. P. Cook, whose death I accidentally learnt, on the 18th November last, in a house at Thames Ditton, from Mr. P. Clarke, a gentleman who is a tea-planter in Assam. This sad news was recorded in an Indian paper, the *Assam Gazette*, of October 25, 1880, which, at my request, was forwarded to me a few days after.

I now give my correspondent's letter to me, dated 14th February, 1880, and received on the 12th of March, 1880:—

"Kassia Hills, Assam.

"DEAR SIR,—You must have thought it very remiss on my part, allowing your letter to remain so long unanswered, but a sudden and unforeseen calamity, in the death of my only brother, Major Cook, Deputy-Assistant Adjutant-General, Eastern Counties Districts, who fell mortally wounded while leading on his men in the final assault on Khonoma, in the Naga Hills, has entirely prevented me paying any attention to entomological pursuits for the last three months.

"My poor brother having died possessed of a good deal of landed property in no less than three of our Indian hill stations, I have been travelling incessantly winding-up his affairs; in fact, I may with perfect truth say, that for the last two months and a-half, I have been living in railway carriages and on board river steamers.

"The old adage, that misfortunes rarely come singly, I have found in my case to be true, for on my return to this station last Thursday, I found that my bungalow had been burnt to the ground through the gross carelessness of a drunken syce. Nothing was saved, a magnificent and most expensive library of entomological works, 47 large cabinets of specimens (my own private collections), my gleanings for over 26 years in Sumatra, Java, New Guinea, Borneo, Calesbes, the Philippine Islands, and Japan, over 4,000 specimens ready to forward to England, all was lost just through the carelessness of a drunken wretch capsaing a lamp in my stables.

"I keep up a staff of eight Rhapsias, whom I have thoroughly trained for the work of collecting in the malarious jungles, where it is almost certain death for an European to sleep one night. I likewise have a large circle of friends and acquaintances among the officers and tea planters in the districts, all of whom I have

persuaded to collect for me, and who send me what they have been able to accumulate, as always take the field myself in March, and generally leave the forests before autumn is vanced, many thousand insects pass through n annually.

"As before stated, all my large stock of reserve has been lost in the fire; however, I hope in tl of a month, or six weeks at the latest, to be ab patch you a first consignment. I will pay p attention to your wishes about the cocoons various silk moths, and have already receive from two intimate friends who, perhaps, are t most eminent entomologists in India, Capt. and Col. Jones, both officers in the Royal Ex. They inform me that they have written to some correspondents in other parts of the Himalayas cure cocoons of such of the silk moths as are curable here. I can, however, promise to send number of cocoons of the following species:—*assamensis*, *Attacus atlas*, *Actias selene*, and *manas*. Will you kindly write to me by first m the receipt of this, what cocoons do you consi valuable, and the particulars that may be use in forwarding them.

"I shall probably be away in the wilds of th hill forests, but your letter will be forwarded c out delay. I should very much like to see your reports, it would give me very much ple read them, and in return, will forward you s my book on the genus *Deilephila*, which oug completed and published next month. It inc the known Asiatic species of *Cherocampa*, *Macrotila*, *Smerinthus*, and the illustrations, ove number, have taken me nearly three years to c as I have drawn each moth in water-colours after capture as possible, with representation egg, caterpillar, and tree on which they live.

"As the season is not sufficiently advanced the field, hard frosts and bitterly cold winds pr at this lofty elevation where anything in the v vegetation is parched and dried up, I am, at hard at work on the illustrations for a work of Marshall's, on "Our Indian Lepidoptera;" wh pleted it will be the most perfect work on lepidoptera ever given to the world, over 2,000 sp illustrated.

"About a dozen of us are starting a new s entomological magazine; how it will answer I tell; fortunately, all men concerned in it are t well off, so, if it fails, we shall none of us be ru

"Hoping to hear from you in reply to this, giv all the information in your power about the c I remain, &c."

After the receipt of this letter, to which I three times, I never received any communicatio my correspondent, and, as above stated, it was accident that I heard of his death.

ALFRED W.

110, Clapham-road, London, S.W.

## CORRESPONDENCE.

### THE PARTICIPATION OF LABOUR IN PROFITS OF ENTERPRISE.

If it is not out of order, before the close of cussion upon this important subject, which I sh no opportunity of attending, I should like to few suggestions upon a question which I h peculiar advantages of studying, from both an and employer's point of view.

That there is a great amount of wasted a placed energy existing among workmen scarcely

ment; and it has always appeared to me, that other part of it arises from the want of personal in the quantity or quality of work done; where is the only object to be gained, piece-work meet every requirement in this direction, the being regulated by the natural law of supply and demand, while bringing the best man to the front; where quality is required, piece-work as a rule is a failure, and some scheme of participation in is the only reasonable solution of the problem. I submit that any scheme of this kind will prove if it fails to recognise the following conditions, that the margin between a workman's earnings and daily requirements is too small to admit of its being used to meet trade losses, even supposing work would be found willing to incur such a risk; and that investment will never be popular among the British workmen.

Apply with these conditions, the following principle seems to me to be the correct one upon which to base any scheme of participation, and I feel sure would be found applicable to a large number of our masters and men—namely, that if a workman, by dint of increased exertion, obtains a greater share of the ordinary profits of trade, he is entitled to one half of the amount so earned, and to leave the other half in the hands of his employer; to cover the risk of loss, for which he has not provided. In the case of old and well-established concerns, this standard of ordinary profit is fairly arrived at, by taking the average of the gains and losses balance for a number of years, excluding a period of both inflation and depression; and with new concerns, by a fixed percentage interest upon capital invested, and a share of profit. But, in all cases, the amount divisible to the workmen to be paid to them annually in proportion to their production of a qualifying certificate of maximum of service, based upon a system of payment given over with their wages. The employer, in the face of continued losses, would be justified in stopping, as now, either of reducing the wages, or of closing his business altogether; whilst the payment of a yearly bonus—in some cases probably much larger amount than the workman was in the habit of receiving at one time—would lay the foundation of thrift, otherwise unthought of for want of management.

Well-known antipathy of trades unions to piece-work, in my opinion, done more to estrange the feeling which should exist between capital and labour than anything else, and probably has stifled, at the same time, many comprehensive schemes on the part of employers for mutual benefit.

J. B. SQUIRE.

House, Durning-road, Liverpool.

## RIVER CONSERVANCY BILLS.

I enclose the honour last week to print an abstract of the remarks I made on Mr. Creswell's paper. They are all very accurate, but there are two points which I appear to have been misunderstood by the Committee.

I am made to say that I think the classification of the bills should take place before the formation of the Conservancy, whereas the exact opposite is my opinion. I think it is their duty and their authority should be formed first, and then, when Government sanction is sought, the particular works a Board may wish to carry out, and the proper time for the Local Government to be the aid of its inspector, to go into the question of the far different lands will be benefited. It is remembered that what any works are worth to the country must depend upon the character and the nature of the works; and what proportion he ought to be settled when the works have been de-

vised upon, and when their locality and probable effect have been announced.

If all the owners in a watershed have, before a Board can be formed, to submit to being taxed in a certain manner for river improvements still undivided in localities still unfixed, you may depend upon it more fighting than flood prevention will be the result.

2nd. I am made to say that if weirs were removed from rivers, "it would not make any difference in the level of the water." What I did say was to this effect, that there are many weirs on the Thames up which boats can be rowed during extreme floods, and that the fall at the weir, which, in such cases, must be extremely small, is an outside measure of the improvement that could result from the removal of the weirs.

March 2nd, 1881.

## OBITUARY.

**William Arnot, F.C.S.**—Mr. Arnot, a consulting chemist and chemical engineer, of Edinburgh, died on the 9th February, at the early age of 38, at Bridge of Allan, to which place he had gone for change of air. Although his health had been broken by a severe attack of rheumatic fever last winter, his death was somewhat sudden, and he was announced to read a paper before the Society of Arts, on the 9th of the present month, on "Improvements in the Treatment of Esparto for the Manufacture of Paper," a subject to which he had paid special attention. In the winter of 1877, he delivered a course of six Cantor lectures, on "The Technology of the Paper Trade." Mr. Arnot was born in Falkirk, where his father was an iron-monger, and in early life he removed to Glasgow to study chemistry under Dr. Penny. He was subsequently appointed chemist to Messrs. Macfie's Sugar Refinery, but, in 1868, he returned to Scotland to assist Dr. Penny in the work of purifying the River North Esk, and shortly afterwards, on the doctor's death, he was appointed successor. In 1873, he opened large chemical works at Kirkintilloch. This undertaking not being successful, he removed to Edinburgh. Mr. Arnot was elected a member of the Society of Arts in 1877.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MARCH 9.—"Ascents of Chimborazo and Cotopaxi, in 1880." By EDWARD WHYMPER.

\* \* \* Members are requested to take notice that this meeting will be held at the South Kensington Museum. For conditions of admission see page 289.

MARCH 16.—"The Compound Air-Engine." By COL. F. BEAUMONT, R.E.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. PREECE.

APRIL 6.—"The Discrimination and Artistic Use of Precious Stones." By PROFESSOR A. H. CHURCH, F.C.S.

APRIL 27.—"Five Years' Experience of the Working of the Trade Marks' Registration Acts." By EDMUND JOHNSON.

Dates not yet fixed:—

"The Manufacture of Glass for Decorative Purposes." By H. J. POWELL (Whitefriars Glass Works).

"Buying and Selling; its Nature and its Tools." By PROFESSOR BONAMY PRICE, M.A. LORD ALFRED S. CHURCHILL will preside.

"The Electrical Railway, and the Transmission of Power by Electricity." By ALEXANDER SIEMENS.

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MARCH 15.—"Diamond Fields of South Africa." By R. W. MURRAY.

APRIL 5.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.

The meeting previously announced for April 7 will be held on May 12.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

MARCH 4.—"The Results of British Rule in India." By J. M. MACLEAN. Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., will preside.

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

##### *Syllabus of the Course.*

##### LECTURE I.—MARCH 7.

The production and regulation of electric currents. The laws of the mutual induction of currents and magnets.

##### LECTURE II.—MARCH 14.

The measurement of electric currents. Efficiency of magneto- and dynamo-electric machines. Heating effects of the current.

##### LECTURE III.—MARCH 21.

Use of magneto- and dynamo-electric machines for electric lighting. Electric lighting by means of the arc.

##### LECTURE IV.—MARCH 28.

Subdivisions of the electric current. Incandescent lamps. Luminous effects of electric currents in a vacuum, and in various gases.

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Three Lectures.

April 25; May 2, 9.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 7TH...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Professor W. G. Adams, "The Scientific Principles Involved in Electric Lighting." (Lecture I.)  
Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. T. Aveling, "Tithes, Ordinary and Extraordinary."  
Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.  
Institute of Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. H. H. Collins, "Sanitation as an important increment of value in House-Property."  
Society of Engineers, 6, Westminster-chambers, 7½ p.m.  
Medical, 11, Chandos-street, W., 8½ p.m.  
Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Mr. E. Brown, "Language and the Theories of its Origin."

London Institution, Finsbury-circus, E.C. 5  
Prof. A. H. Sayce, "The Gods of Canaan."  
TUESDAY, MARCH 8TH...Medical, 11, Chandos-street, Anniversary.

Royal Institution, Albemarle-street, W., 3  
E. A. Schiffer, "The Blood." (Lecture VI  
Central Chamber of Agriculture (at the Ho  
SOCIETY OF ARTS), 11 a.m.

Medical and Chirurgical, 53, Berners-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, W. S.W., 8 p.m. 1. Discussion on Sir William paper, "Tide-Gauge, Tidal Harmonic and Tide-Predictor."

Photographic, 5A, Pall-mall East, S.W., 8½ p.m. by Mr. Payne Jennings.

Anthropological Institute, 4, St. Martin's-p 8 p.m. 1. Exhibition of rubbings taken

posts and window-frames in New Zealand note from Prof. Max Müller. 2. Mr. I

"Mote on Assam Dwellings." 3. Major I thorpe, "A short account of the Wild Tribe the so-called Naga Hills, on our North-East of India."

Royal Horticultural, South Kensington, S.W. WEDNESDAY, MARCH 9TH...SOCIETY OF ARTS (in of the South Kensington Museum), 8 p.m. Whymper, "Ascents of Chimborazo and (1880)." 1. Description of Parts of the Skel

Anomodont Reptile (*Platyodonosaurus robr* Part 2. The Pelvis." 2. Prof. R. Owen, "Theriodontia, with a Description of a New Species (*Elurodonosaurus felinus*, Ow.)." 3.

Dawson, "Additional Observations on the Geology of British Columbia and Adjacent

Graphic, University College, W.C., 8 p.m. Microscopical, King's College, W.C., 8 p.m. Michael, "A Species of *Acarus* Believed

recorded." Royal Literary Fund, 10, John-street, Ad 3 p.m. Annual Meeting.

Sanitary Institute of Great Britain, 9, Condui 8 p.m. Adjourned Discussion upon Mr. W. I paper, "The Law in Relation to Sanitary P

Royal United Service Institution, Whitehall- Lieut.-Col. E. F. Chapman, "The March to Kandahar in August, 1879, and the Batt

September." THURSDAY, MARCH 10TH...Royal, Burlington-house, V

Antiquaries, Burlington-house, W., 8½ p.m. London Institution, Finsbury-circus, E.C.,

W. Morris, "The Prospects of Architectur Civilisation."

Society for the Encouragement of Fine Arts street, W., 8 p.m. Mr. Walter J. Allen, reference to the Stage." The Sequel.

Royal Institution, Albemarle-street, W., 3 p. Houghton, "The Picture Origin of the Characters." (Lecture II.)

Inventors' Institute, 4, St. Martin's-place, W. Royal Society Club, Willis's-rooms, St. Ja 6 p.m.

Mathematical, 22, Albemarle-street, W., 8 p. FRIDAY, MARCH 11TH...Royal United Service Institu

hall-yard, 3 p.m. Vice-Admiral W. M. Dr Tactics."

Royal Institution, Albemarle-street, W., 8 p. Stuart Blackie, "The Language and Liter Scottish Highlands."

Astronomical, Burlington-house, W., 8 p.m. Geologists' Association, University College, V

Visit to the British Museum, under the dir Stuart V. Ridley.

Quekett Microscopical Club, University Co 8 p.m.

Clinical, 43, Berners-street W., 8½ p.m. New Shakespeare, University College, W.C., t

Brinsley Nicholson, "The 'Tempest' for older Play." 9. Mr. Herbert A. Evans, " of 1 and 3 'Henry IV.'"

Royal College of Physicians, Pall-mall East, (Gulstonian Lecture.) Dr. Compland, (Lecture I.)

Folk Lore Society, 22, Albemarle-street, W., J. Sibree, jun., "The Oratory, Songs, Folk Tales of the Malagasy."

SATURDAY, MARCH 12TH...Ladies' Sanitary Assoc House of the Society of Arts), 5½ p.m. Richardson, "Domestic Sanitation or Heal (Lecture V.)

Physical, Science Schools, South Kensington. Col. Festing and Capt. Abney, "The Absor of Organic Bodies."

Royal Botanic, Inner-circle, Regent's-park, Royal Institution, Albemarle-street, W., 3

Stuart Poole, "Ancient Egypt in its Comy ti-ns." (Lecture IV.)

## AL OF THE SOCIETY OF ARTS.

No. 1,477. Vol. XXIX.

FRIDAY, MARCH 11, 1881.

*Lectures for the Society should be addressed to the Secretary  
John Street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

1st lecture of the third course was delivered  
day, 7th inst., by Professor W. G. Adams,  
on "The Scientific Principles involved in  
Lighting." The lecturer commenced  
description of the production and regula-  
electric currents, and then illustrated the  
the mutual induction of currents and  
Arrangements have been made for the  
n of various incandescent and other lamps  
at the third and fourth lectures, and for  
see the British Electric Light Company  
dly promised to lend Gramme machines,  
Mr. Robey to lend a steam-engine to drive  
ines.

tures will be published during the summer

## ALBERT MEDAL.

council will proceed to consider the award  
Albert Medal for 1881, early in May next.  
al was struck to reward "distinguished  
promoting Arts, Manufactures, or Com-  
and has been awarded as follows:—

, to Sir Rowland Hill, K.C.B., F.R.S., "for  
service to Arts, Manufactures, and Com-  
the creation of the penny postage, and for  
reforms in the postal system of this country,  
ts of which have, however, not been confined  
ntry, but have extended over the civilised

, to his Imperial Majesty, Napoleon III., "for  
hed merit in promoting, in many ways, by his  
exertions, the international progress of Arts,  
ares, and Commerce, the proofs of which are  
y his judicious patronage of Art, his enlight-  
neral policy, and especially, by the abolition  
its in favour of British subjects."

i, to Professor Faraday, D.C.L., F.R.S., for  
tes in electricity, magnetism, and chemistry,  
their relation to the industries of the world,  
argely promoted Arts, Manufactures, and  
,"

, to Mr. (afterwards Sir) W. Fothergill Cooke  
onor (afterwards Sir) Charles Wheatstone,  
in recognition of their joint labours in estab-  
; first electric telegraph."

, to Mr. (now Sir) Joseph Whitworth, F.R.S.,

LL.D., "for the invention and manufacture of instru-  
ments of measurement and uniform standards, by which  
the production of machinery has been brought to a  
state of perfection hitherto unapproached, to the great  
advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the  
Institute of France, For. Memb. R.S., Chevalier of the  
Legion of Honour, &c., "for his numerous valuable re-  
searches and writings, which have contributed most im-  
portantly to the development of food economy and  
agriculture, to the advancement of chemical science,  
and to the benefits derived from that science by Arts,  
Manufactures, and Commerce."

In 1870, to Ferdinand de Lesseps, "for services  
rendered to Arts, Manufactures, and Commerce, by the  
realisation of the Suez Canal."

In 1871, to Mr. (now Sir) Henry Cole, C.B., "for his  
important services in promoting Arts, Manufactures,  
and Commerce, especially in aiding the establishment  
and development of International Exhibitions, the de-  
velopment of Science and Art, and the South Kenning-  
ton Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S.,  
"for the eminent services rendered by him to Arts,  
Manufactures, and Commerce, in developing the manu-  
facture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S.,  
"for his chemical researches, especially in reference to  
saponification, dyeing, agriculture, and natural history,  
which for more than half a century have exercised a  
wide influence on the industrial arts of the world."

In 1873, to C. W. Siemens, D.C.L., F.R.S., "for  
his researches in connection with the laws of heat, and  
the practical applications of them to furnaces used in  
the Arts; and for his improvement in the manufacture  
of iron; and generally for the services rendered by him  
in connection with economisation of fuel in its various  
applications to the Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished  
French statesman, who, by his writings and persistent  
exertions, extending over many years, has rendered  
essential service in promoting Arts, Manufactures, and  
Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S.,  
Astronomer Royal, "for eminent services rendered to  
Commerce by his researches in nautical astronomy, and  
in magnetism, and by his improvements in the applica-  
tion of the mariner's compass to the navigation of iron  
ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S.,  
member of the Institute of France, "the distinguished  
chemist, whose researches have exercised a very material  
influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L.,  
F.R.S., "because of his distinction as an engineer and  
as a scientific man, and because by the development of  
the transmission of power—hydraulically—due to his  
constant efforts, extending over many years, the manu-  
factures of this country have been greatly aided, and  
mechanical power beneficially substituted for most  
laborious and injurious manual labour."

In 1879, to Sir William Thomson, LL.D., D.C.L.,  
F.R.S., "on account of the signal services rendered to  
Arts, Manufactures, and Commerce by his electrical  
researches, especially with reference to the transmission  
of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L.,  
"for having established, after most laborious research,  
the true relation between heat, electricity, and mechan-  
ical work, thus affording to the engineer a sure guide in  
the application of science and industrial pursuits."

The Council invite members of the Society to for-  
ward to the Secretary, on or before the 23rd of  
April, the names of such men of high distinction as  
they may think worthy of this honour.

### COMMITTEE ON PREVENTION OF STREET ACCIDENTS.

A meeting of the Committee appointed by the Council to confer with a deputation from the Society for Preventing Street Accidents, was held on Monday, March 7, at the House of the Society of Arts. Present:—Sir Rutherford Alcock, K.C.B., Mr. G. C. T. Bartley, Mr. Andrew Cassels, and Sir Henry Cole, K.C.B., with Mr. H. Trueman Wood, Secretary, on the part of the Society of Arts; Viscount Templetown, Sir Hastings Doyle, Dr. D. H. Goodsall, Mr. W. R. Philp, the Rev. William Rogers, Mr. W. E. Stevenson, and Mr. E. C. Keevil, Secretary, on the part of the Society for Preventing Street Accidents. It was resolved to recommend the Council to appoint a deputation to wait upon the Lord Mayor.

## PROCEEDINGS OF THE SOCIETY.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday, February 24, 1881; Captain Sir GEORGE NARES, R.N., K.C.B., F.R.S., in the chair.

The paper read was—

### DEEP-SEA INVESTIGATION, AND THE APPARATUS EMPLOYED IN IT.

By J. Y. Buchanan, F.R.S.E., F.O.S.

Deep-sea investigation, in the sense of exploring the surface of the ocean with the view of discovering new lands, and so determining the boundaries of the sea, has, in all ages, commanded the attention of the more civilised races of mankind, and the most adventurous of their members have ever engaged with enthusiasm in its pursuit. It is probable that the first voyages were undertaken, less with a view to satisfy curiosity, than to render travelling from place to place more expeditious and less irksome. It was not until the mariner's compass had been introduced into Europe, in the 12th century, that long voyages, out of sight of land, could be undertaken; although the enterprise of the Mediterranean mariners enabled them to take their ships as far as Britain without any such aid; and no one who is at all acquainted with practical navigation, will deny the difficulty and the danger of the undertaking. The adoption of the compass as a standard of direction, and the immense amount of valuable property which was consequently risked on the faith of its infallibility, raised a strong interest in the study of the behaviour of the magnetic needle in different localities, especially at sea, resulting in the discovery and investigation of the magnetic

nised phenomenon to be taken into account in all questions affecting a ship's position on his voyage, which ended in the discovery of America, Columbus crossed the Atlantic in the position of a line of "no wind" west of the Azores. Papal decree, made the bound of the kingdoms of Portugal and (the determination of its position) of factitious importance which was of much valuable geographical importance for the first voyages for scientific purposes taken for determining the magnetic variation at different places on the ocean, subject to continual variations from time to time is like a future motive for frequent navigation.

It was in connection with magnetic phenomena that a convenient method of graphical representation of the relation between isolated observations of its first extension. In an ordinary map one of the principal features is the intersection of the sea surface, as deduced from observations at different points. With greater detail the height of points inland above the sea is determined, from which profiles are drawn of equal height on these profiles and their projections on the sea surface in the map as lines of equal height generally called contour lines of the land below the sea is the method of graphic representation in a chart, however, all the observations of depth are entered, while in the configuration of the contour lines deduced from the individual observations, in rendering the results of magnetic observations convenient to the public, navigator, the results of variation at the different points in a chart, and points of connection by lines drawn at intervals from degree to degree, or in the case of sea and land the magnetic constant is nowhere abruptly, consequently contours of moderately regularity wants of navigation. On land, especially in view of consisting largely of igneous rocks, a constant constituent of oxide of iron or loadstone which it is present in one to another, often varies. The consequence is, therefore, different directions at localities; that a survey of such magnetic material, according to the method on solar or magnetic

The employment of the results first of geodetic observations, was extended to the representation of terrestrial magnetic force have since been largely in the distribution of other quantities of water, and of plants

it, however, as is the investigation of phenomena at sea, it is not my intention further to it to-night; it is enough to state that the interest which it for navigation was the moving cause of the earliest maritime scientific investigations. Our concern is with the determination of the depth of the ocean, of the physical character of its waters, and of its bottom, and with the discovery of life in it.

The problem of deep-sea investigation is to the extent of the ocean, its size, its superficial extent and limits are determined by the surveyor. In order to map out a part of the sea, there is only one method, the direct determination of the depth at various places.

A ship is "in soundings," the depth is determined at frequent intervals by a "leadman" who takes some convenient place on the outside of the ship, whence he can throw forward the lead line, which he carries in his hand. The lead line is from 20 to 25 fms. long, and it is conventionally marked with rings at 2, 3, and 10 fathoms, white rings at 5 and 15, red bunting at 7 and 17, blue at 13, and with two knots at 20 fathoms.

The lead is a long, finely-tapered block, of 14 lbs. weight; it has a recess at the end and is perforated at the other end for the insertion of the line. This instrument is used while the ship is in motion. The man with the duty swings the lead backwards and forwards, and even completely round a circle, in order to generate the momentum to carry the lead well in the ship before it touches the water. It is rapidly, whilst the leadman's position is kept to the spot where the lead touched the bottom.

When the line has thus been brought in, the depth is ascertained by observations on the line. It is obvious that by this method, but effective, method of sounding, the depth which can be so ascertained depends on the speed of the vessel, and in some cases on the skill and strength of the leadman.

Under ordinary circumstances, the method is effective in depths up to twelve or fifteen fathoms; in this degree of efficiency suffices for most purposes.

Usually, however, it is advisable to sound depths, without the ship being necessary. The simplest method of doing so is as much as possible the ship's way, to carry the line well forward, to leave it to sink. Here the speed of the vessel should be so regulated that the lead reaches the bottom before it is passed completely over it. With care, soundings can be obtained in this way at depths must not be much above thirty fathoms.

The object is to sound in ocean water, and must be prepared to meet with depths of up to a thousand fathoms, it is essential that the ship be kept stationary, and if hemp line be used, heavier weights must be employed. At great depths is one of the most im-

portant operations connected with deep-sea investigations, and it is only within the last thirty years that it has received any very great attention. Probably the first attempt at deep-sea sounding was made by Captain Constantine John Phipps, during his Arctic voyage, in the year 1773, when he was accompanied by Dr. Irving, who made a number of very valuable determinations of the temperature of the sea water at different depths, besides fitting the vessel with one of the earliest stills, which worked well, and supplied the crew with fresh water during the whole cruise. Phipps' deepest sounding appears to have been 683 fathoms. For this purpose, all the lead line in the ship was used, and a lead weighing 160 lbs., which appeared to have sunk about ten feet into the mud, a soft blue clay. With this was sent down a water-bottle, of Dr. Irving's construction, and the water brought up had a pressure of 40° Fahr., that of the surface being 55° Fahr. The density of the water was also measured, and Cavendish's self-registering thermometers were used. So that, at this early date, the methods and objects of deep-sea investigations were perfectly understood. What prevented much work being done was chiefly the want of steam. But little advance was made in this branch of research until after the termination of the French war. In 1818, Captain John Ross made his well-known voyage of discovery to the Arctic seas, in H.M. ss. *Isabella* and *Alexander*. During this voyage, he paid great attention to deep-sea investigation, and invented, and had constructed, one of the earliest satisfactory instruments for bringing up a considerable quantity of the bottom-mud in deep water. He, himself, gives the following account of his instrument and its performances, in the appendix to the account of the voyage:—

"This instrument was invented by me, on board his Majesty's ship *Isabella*, in the early part of our voyage to the Arctic Regions. Many fruitless attempts had been made to procure substances from the bottom of the sea in deep water, by the instruments with which we were supplied, and I had an opportunity of observing the reasons of this failure, which led to the discovery of that which I am about to describe, and which, in almost every instance, completely succeeded in accomplishing that desirable object, of bringing up substances of any description, in considerable quantity, from any depth; but it has also been found to preserve the temperature of any substances, if they are soft, until it can be measured by the thermometer, and by that means the temperature of the earth can be nearly ascertained at any fathomable depth. In Melville Bay, on the 1st of August, it brought up from four hundred and twenty fathoms some soft mud, into which the thermometer was immediately immersed, and it gave 29½°. At the same time, the self-registering thermometer, at the depth of two hundred and ten fathoms, gave the same temperature. In Prince Regent's Bay, in four hundred and fifty-five fathoms, it gave the same temperature. In the entrance of Lancaster Sound, at the depth of six hundred and seventy-four fathoms, the temperature of the mud was also found to be 29½°; and at the highest part of that inlet in which we sounded, the mud was found to be, in six hundred and fifty fathoms, 29°.

"On the 6th of September, in latitude 72° 23' N., and longitude 73° 07' W., we sounded in 1,010 fathoms, from which depth the instrument brought up 6 lbs. of very soft mud. The next day being quite calm, we tried the temperature of the sea at five, six,

seven, eight hundred, and a thousand fathoms, and found its temperature decrease, from 35 gradually to the same temperature as the instrument gave it, which was 28½. Although the instrument may not bring up the mud at the exact temperature of that at the bottom, it may be supposed that it cannot have suffered much alteration, from its agreeing so nearly with the self-registering thermometer, and that, if it has altered, it must be to increase the degree of temperature; hence, it may always be inferred that the mud at the bottom is not of a higher temperature than that brought up by the instrument. The reasons for so little alteration taking place in the closeness with which the instrument confines the mud, which is such as not to allow even the water to escape. If the instrument strikes among stones which are small enough to get between the forceps, it will bring up as many as are enclosed in them; in one instance, it brought up a stone (which weighed two pounds and a half) from 300 fathoms, and, in another, it struck a rock, and cut a piece out, which it brought up from 216 fathoms. The instrument was made from the model by the ship's armourer, and succeeded on the first trial.

"To use the deep-sea clamma, it is necessary to be provided with whale lines, such as are used by the Greenland and South Sea ships, which are two and a half inches in circumference, made of the best hemp, and very pliable and easily coiled; the lines ought to be spliced together, and faked, or coiled, so as to run quite clear on the fore part of the ship's decks. In very deep water it is necessary that it should be calm, or nearly so, to be certain that soundings are obtained in 500 fathoms, but, in a light breeze, the instrument may be hung to a boat, and towed in the direction of the ship's drift, and if there is any wind, it is best to lower all the sails down. An outrigger, fitted with a block, should be fixed in the weather-quarter, through which the line ought to be rove and bent to the instrument, when it ought to be lowered until it is a fathom below the surface, and then let go. The instruments and lines may, however, be made for different depths, and used accordingly. For the North Sea, I would recommend one of fifty pounds."

The cast-iron sinker of the one actually used by Captain Ross was a long, hollow, parallelepiped, weighing one hundredweight.

About the same time as Sir John Ross was prosecuting his voyages on behalf of the Government, Scoresby, in the pursuit of his trade as a whaler, was collecting most valuable information. Of all the navigators who have combined with the due discharge of their duties as sailors the scientific investigation of the conditions of the ocean, the younger Scoresby is certainly the one most imbued with the spirit of the philosopher. The problems to be solved seem to present themselves at once to his mind divested of all irrelevant matter, and he attacks them directly and successfully. In sounding at great depths, for instance, he at once recognises that when the ordinary deep sea line and lead are used, the increasing weight of line, in proportion as more of it is required, renders less certain the determination of the moment when bottom is reached. He determines the density of the water with a thermometer with large bulb and narrow stem, and he gives a table for correcting observed specific gravities for temperature, which shows that he knew that sea water did not attain a maximum of density at the same temperature as distilled water. The following passage from his "Arctic Voyage" will show how thoroughly he knew the nature of the work which he had taken up:—

"The difficulty of getting satisfactory great depths, arises principally from the intimation given when the lead strikes. This uncertainty is increased by using a thin line if a lead of a hundred pounds were used attached to it would require to be so thick depth of six or eight hundred fathoms, if the line, even in water, would be so many times that of the lead, that scarcely any effect observed when it should reach the bottom always prefer a light lead, and a very small lead of 20 pounds, I have sounded in 500 fathoms, and felt assured that if it had bottom I should have observed it, for the line in use was not above twice as heavy; so that the diminution of one-third of the weight have been very observable. But with a heavy thick line, where the strength of several men to haul it up, there can be no evidence, with weighing, of any trifling alteration in weight. Hence, if the lead is found to have bottom, there can be no assurance that a quail line, as well as the lead, has not also been on. To a 20 lb. or 25 lb. lead, I generally attach fathoms of common log-line, where there is apparatus along with it, and to this a line and finish with a deep-sea line, thus increasing in thickness with the increase of weight to be and having the whole of such a weight can be held in the hand, and the least step perceptible."

After showing how, from observing whale fishing, he had often been able to draw correct conclusions as to the depths of water, the amount of line which they would when running perpendicularly down relates the following story, from the lips of his father, who was also a whaler:—

"At great depths, the effect of the pressure of the sea is not a little curious. My father met the following singular instance, in the year 1778, he had taken from his log-book. On the 3rd of the chief mate of the *Hermes*, of Whitby, father then commanded, struck a whale, and all the lines out of the boat before assisting and then dragged the boat under water, the whale creeping to a piece of ice. When the boat came to the surface to 'blow,' it was struck a second time, and soon afterwards killed. The moment it began to sink, which, not being a usual circumstance, excited some surprise. My father, who was assisting at the capture, observing the whale seized a grapple, fastened a rope to it, threw the tail of the fish, and fortunately hooked it. The whale began to sink, but the line being held fast in length stopped it, though not until it was such that the boat was in danger. The 'bight' or loop of a rope being thrown round the fish, and allowed to drop enclosed the line belonging to the whale, which was found to be the cause of the accident observed. Immediately the harpoon alighted on the whale, and was, with the line and boat at the point of being lost, when it was hoisted by the encompassing rope. The fish being hoisted from the weight of the line and boat, rose face; and the strain was transferred to the harpoon, which was connected with the disengaged harpoon. Imagining that the sunken boat was eaten up by rocks at the bottom of the sea, and that the current on the line produced the extraordinary proceeding himself to assist in hauling up the strain upon the line he estimated at three-fourths of a ton, the utmost power of men being requisite to overcome the weight."

havior operation of hauling the line in occupied several hours, the weight continuing nearly the same throughout. The sunken boat, which before the accident would have been buoyant when full of water, when it came to the surface required a boat at each end to keep it from sinking. When it was hauled up the ship, the paint came off the wood in large shreds, and the planks, which were of wainscot, were completely soaked in every pore as if they had lain at the bottom of the sea since the Flood. A small apparatus that accompanied the boat in its journey through the deep, consisting chiefly of a piece of tin foil, about fifteen inches square, happened to fall aboard, and though it originally consisted of light tin, sunk in the water like a stone. The tin was rendered useless; even the wood of which it was made, on being offered to the cook as fuel, was rejected as incombustible."

The incident is exceedingly interesting, as being, perhaps, the first occasion on which the effect of enormous pressure produced by a column of water was directly observed. It will be observed that the wood, though painted, got completely water-logged, while the whale, which must have resided to nearly the same depths, retained its

The man introduced by the Americans, of using a line and a heavy weight, sacrificing both at accuracy, was one which, with a little elaboration, could have been made to give very accurate measurements of depth. And, indeed, when it was found that ordinary observation or feeling was not sufficient to indicate when the shot had reached the bottom, the practice of observing the time which successive equal lengths of the line took out, which has since been so useful, was deduced. It is worthy of remark that, at this early date (about 1850), iron wire was used instead of twine, by Lieutenant Walsh, of the U.S. Fish Commission.

The telegraphic enterprise began to develop all deep-sea sounding became of great practical importance, and, since the date of the first Atlantic cable, has been carried on both by Governments and commercial companies, with all the energy and prospect of prospective money-making. For the telegraphic engineer, however, it was not enough to know the depth of the water; it was of almost equal importance for him to know the nature of the ground on which his cable was

The invention, in 1834, by passed Midshipman Brooke, of the U.S. Navy, of a contrivance to take the weight used to carry down the sounding-line, while it enabled a specimen of the bottom to be brought up, was of great importance rendering easier and more accurate the survey of the ocean bed. Brooke's sounding apparatus consisted of a cannon-ball, with a hole drilled through it. Through this hole passed a straight rod, fitted at its upper end with peculiar disengaging hooks. The weight was slung to these hooks means of a wire, which passed from a ring, which was slipped over the rod under the weight, on each side of the cannon-ball to the hooks. The sounding-line was attached to eyes in these hooks, and as long as the lower end of this rod was resting on any thing, the weight was kept steady in its place, and available for taking out the sounding-line. As soon, however, as bottom was reached, and this rod came to be supported on the lower end, the hooks at the upper end fell

forward, and allowed the wire to disengage itself. The weight was thus released, and, on the line being pulled up, the rod came away through the perforation of the shot, and brought with it specimens of the mud in small quill tubes fitted in a recess in the lower end of the rod. The principal object which Brooke had in view was to disengage his weight, and his contrivance for doing so is excellent, the moment the end of the rod touches bottom, the weight slips off. In order, however, to gain the greatest possible amount of information from a deep-sea sounding, it is advisable to arrange so that the tube, which is now used in similar machines instead of a rod, should penetrate the ground as far as possible. This is attained by so arranging the apparatus that the weight does not detach at the moment of striking bottom, but only when hauling in is begun. This condition is fulfilled in the instrument used in H.M.S. *Bulldog*, by Sir Leopold M'Clintock, in the year 1860. It is a modification of Sir John Ross's "deep-sea clam," in which the weight presses the clam into the ground, until, on pulling in the line, it is thrown off and left at the bottom. This instrument brings up a specimen of what is at the surface of the ground, but does not give a sample of what is below.

The "Fitzgerald" sounding machine was used in the expedition in H.M.S. *Lightning*, in the summer of 1868, when it gave satisfaction. It was tried on board the U.S.S. *Tuscarora*, and Commodore Belknap reports unfavourably of it. From its irregular form, it offers considerable resistance during descent, and in coming up gets the line full of kinks.

At the latter end of 1868, Captain Shortland was ordered to make soundings between Bombay and Aden, and for this purpose he devised and constructed on board his ship, the *Hydra*, a modification of Brooke's apparatus, which gave great satisfaction, and was afterwards used in the *Porcupine* and the *Challenger*. The general arrangement is the same as in Brooke's apparatus; instead, however, of a rod, he has a brass tube, which passes through the centre of the weight, which consists of one or more cylinders of cast-iron. These weights are slung by a wire to a shallow hook, on the upper part of the rod, which surrounds the brass tube. The lower end of the brass tube carries a pair of butterfly valves, and in the middle of the tube are two conical valves opening upwards, between which a sample of the bottom water is secured, while a specimen of the mud is brought up in the lower segment of the tube. In later instruments, the tube was adapted only for the reception of the mud. When this instrument was used, the tube penetrated into the ground until the weights were supported on the bottom, when a steel spring at the upper end of the rod expanded, and threw the bight of the wire off the hook. The weights were thus released, and on hauling in the line, the tube alone was brought up. During the first year of the cruise of the *Challenger*, this instrument was exclusively used, and it gave general satisfaction. The principal objection to it lay in the smallness of the samples of bottom which it brought up. This was due first to the narrowness of the tube, and also to the butterfly valves at the end. The object of these valves is to keep the samples from being washed out, but they also very materially obstruct the

entrances. With a much larger tube, and a rightly ground valve at the top, better samples would have been obtained.

After the first year of the cruise, the "Hydra" machine was replaced by the "Bailey." This was an apparatus very much on the same lines, but differing from the "Hydra," in the size of tube, and the method of disengaging. The tube, which was of iron, was 5 feet long by  $2\frac{1}{2}$  inches wide, and weighed alone 25 lbs. The hook which carried the wire and weights formed part of a separate brass piece, which telescoped into the iron tube the moment it touched bottom, thus throwing off the weights without utilising them for pressing the tube further into the mud. The weight, however, of the tube alone was so considerable, that this was of little matter, and the "Bailey" usually brought up large samples of mud. It must, however, be remembered, that though the samples were large in quantity, they were principally from the superficial layer. In working with a tube of  $2\frac{1}{2}$  inches internal diameter, a substantial valve of some sort is necessary to prevent the samples falling out when the tube is being brought on board. Such a valve is always a great impediment to the entrance of the mud. It would, therefore, be of great importance to arrange the Bailey tube, so that the weight should be utilised in shoving it into the ground, and also that a greater length of it should protrude beyond the weight. In this way, samples of the mud below the superficial layer would be obtained, and the interest attaching to it is evident. Even with the "Bailey," as it is, we find in several places a red clay at the surface, with white mud below it.

In exploring the seas and lakes of the Highlands of Scotland, I have made extensive use of a form of sounding tube and lead, which I devised for the purpose, and which I have always found to act very well. Its construction is simple, being in effect nothing but a straight brass tube, of one inch diameter, carrying a brass shoulder about one foot from the lower end. A cylindrical leaden sinker of suitable weight is slipped over the upper end, and rests on the shoulder. This line is made fast to a metal eye at the top, and the part of the tube below the shoulder can be unscrewed, and the mud which has been brought up in it squeezed out by a plunger. I have tubes of various lengths, with sinkers of various weights, for work at different depths, and under different conditions. For work in inland lakes it is necessary that every thing should be as light as possible, in order to be suitable for land transport. I use a tube and sinker, weighing in all three pounds; while at sea, with the steam winch available, the sinker weighs generally 28 lbs. Where the bottom is soft mud, these tubes bury themselves in it, and bring up very considerable samples. The samples are also very satisfactory when the bottom is clay; when, however, the bottom is hard sand, or similarly resisting material, the tube impinges suddenly on it, and does not penetrate as deeply as might be wished. The effect is very much as if an attempt were to be made to make a spade penetrate the ground by a sudden blow, instead of a persistent shove. I have designed an arrangement which will enable the tube to exercise a gradual pressure on the bottom, and so to penetrate muds or sands, which offer considerable resistance. Instead of

the weight resting on a metal shoulder, it is attached to the tube, I suspend it by strong india-rubber cords, from hooks near the top of the tube. When the tube strikes the bottom, the valve delivers its blow gradually through the stretch of the india-rubber. I have had a tube of this kind constructed five feet long, and with a valve at the top. This valve at the top is to prevent the contents of the tube falling out of their own weight, when the apparatus has been taken out of the water, and is being brought on board. These tubes bring up samples of the very coarse sand, and Captain Tizard, who used one last year in the surveying vessel *Errant*, found that in *globigerina* ooze it was of use out on the way out. I feel sure that, with india-rubber slings, the tube would be used through the layer of comparatively fine *foraminifera* on the surface, and plug itself at the bottom with the more finely comminuted clayey substance which is usually found there. Where the object is to make soundings, and to get a small sample of the mud on the face of the bottom (as in sounding for telegraph cables), a lead with a blunt end is used, and penetrates only a small way into the mud, and is easily drawn out, bringing a sufficient sample through the axial tube. Mr. Gray, of the Silverton Telegraph Works Company, showed me the sinkers used on board their ships. They weigh thirty pounds, and at the bottom of the tube is a very simple and ingenious valve, made of india-rubber, which is pressed against the side of the tube by the lead, while sinking, and expands and closes the orifice sufficiently to prevent the sample being washed out on coming up.

I now proceed to consider the precautions to be observed in the actual use of these instruments. On stopping the ship, "to make a station," the first operation is to determine the depth. For this purpose the ship, under steam, is brought head to wind, in some cases stern, to wind, and kept as nearly stationary as possible while the sounding is being effected. The method of sounding in deep water is essentially the same whether hemp-line or wire is used. In both cases, it is necessary to lead the end of the line with such a weight that in the deepest water which may reasonably be expected, the velocity of descent shall not be diminished to an excessive extent by the friction of the increasing length of line in passing through the water. Twenty years before the *Challenger* sailed, wire had been used on isolated occasions by the Americans, but it was not until Sir William Thomson took it up, and, with characteristic energy, worked it out into a practical method, that it became really available. When the *Challenger* fitted out, it was decided, after much thought, wisely decided, to use hemp-line, which had already yielded valuable results, and the work of which, even at the greatest depths, was familiar to her captain and officers. During the three and a-half years of her expedition, the extension telegraphic enterprise rendered rapid deep-sounding a necessity, and, in consequence, developed both the apparatus and the art. Now, days, our sailors are almost as familiar with the handling of wire as with that of rope, and no similar expedition would now start without being furnished with apparatus for use

deep sounding. At the same time, it is equally improper to start without a sufficient supply of good hemp line, and the time for working it. For we should never lose our affection for what is novel to blind us to the advantages of what is older-fashioned. For purposes of wire must supersede hemp, because the work better and more expeditiously, and as other departments of the work of an investigation which are better done with

The great advantage of wire above hemp is that at the same tensile strength, we have a line that passes through the water without developing any serious retarding force due to friction, as with hemp line, the retardation so produced is very great. The saving in time and due to the absence of this frictional resistance, is so great that there can be no question as to between wire and hemp when it is referred to number in deep ocean water. To take an example, in water of 1,500 fathoms, a three-pound sinker, with the best hemp sounding line, takes twenty minutes to reach the bottom; with a thirty-pound sinker, the sounding line takes in from twenty-five to thirty minutes. With wire, however, it is thus incomparably better for deep sounding, it has no disadvantages from which the hemp is free. Its only drawback springs from its liability to break. A hemp line may be bent and twisted in any way we please, without its strength being in the least affected; not so, however, with wire. Its whole lifetime it must never suffer a bend, or twist, or nick; if it does, its strength is gone, and if the damaged part is not replaced, an accident is sure to happen. Again, Sir James Thomson has always advocated the use of galvanized wire, which rusts easily when moistened with water. In order to preserve it, the wire, when on the reel, has to be kept in a tank of solution of alkaline with soda or lime. This is a great convenience; but my own experience leads me to the conclusion that there is no reason why galvanized steel wire should not be used, and I find it keeps perfectly well without any special treatment. The objection usually raised to the use of wire is, that the process of galvanizing weakens it. This difficulty I got over by using No. 20 galvanized instead of No. 22 recommended by Sir William Thomson. Steam power is not available for heaving, but wire possesses a very great advantage, for it can be used in any depth, even at very great depths. The U.S. ship *Tuscarora*, which, in 1874, on the route from San Francisco to Japan, made the deepest survey of the water in the Pacific, all her sounding by hand. As an instance of what can be done, I will quote from Kelknap's report, the work done on the January 17th and 18th. Six soundings were made, all in water over 4,000 fathoms in depth. In forty-two observations of the temperature at 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, and 200 fathoms below the surface, the current was observed at 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, and 200 fathoms below the surface. The soundings, the depth being 4,356 fathoms, occupied two hours and twenty-seven minutes. The descent occupying fifty-three, and the ascent ninety minutes.

Steam power at hand—and without it, it

would be folly to attempt deep-sea work—hemp line becomes preferable to wire, where the other branches of deep-sea work are being carried out, such as serial temperature observations, and the collection of water samples from different depths.

Deep-sea thermometers which have been carefully compared with a standard, and which have been used in many soundings, are instruments of very great value, and if lost cannot be replaced by the purchase of new ones. Hence, in making such observations, the conditions which we have chiefly to keep in view is the safety of our thermometers, while, for the completeness of our work, it is important that the temperature should be observed at as many different depths as possible. Now, as the chance of the hemp-breaking is very small when compared with the wire, it is permissible to risk a greater number of thermometers on it than on a thin wire. Therefore, to get the same number of observations with the wire would require the operations of sinking and heaving in to be repeated a greater number of times than with the hemp, and as a thermometer must be allowed a certain time to take the temperature of the water, it will be seen that for such work the wire is in the end no more expeditious than the hemp, and the use of it is attended with considerable risk of the loss of valuable instruments. I am quite convinced, from my own experience, that for all work in depths up to 500 or 600 fathoms, hemp is better for all purposes, because a sinker can be used, which will make it descend nearly as quick as wire, and, with a steam winch, it can be brought up at nearly the same rate.

The wire has, of course, the advantage, that it stows in a much smaller space than ordinary sounding line.

Finally, and to answer the question which is often put to me, whether wire or hemp should be used in a ship's outfit, I would say take both, as they are both useful in their proper places. For determining the depth, use wire; for detail work, with the thermometers and water bottles, use hemp. In this way your sounding will be done expeditiously, and you will not lose your instruments.

With regard to dredging, which forms a very important department of deep-sea investigation, there can be no doubt of the great superiority of wire over hemp rope. The advantage in point of rapidity of work, and of stowage space, is much greater than in the case of sounding. Here, again, we are indebted for a scientific instrument to the enterprise of telegraphic engineers, for if it had not been a necessity for them, it is not likely that we should now have had the very beautiful flexible steel wire hawsers which are to be found in nearly every ship.

Steel wire rope was first used for deep-sea dredging by Professor Agassiz, in the winter 1877-78, and he has continued to use it with great success. His rope "was one and one-eighth inches in circumference, and was composed of six strands laid round a tarred hemp heart. Each of the six strands was composed of seven galvanized steel wires of No. 19 American (No. 20 Birmingham) gauge. The ultimate strength of the rope was 8,750 lbs.; weight per fathom 1.14 lb. in air, and approximately 1 lb. in sea water; price, eight cents. per foot."

In the summer of 1878, I fitted the steam yacht *allard* with a steel wire dredging-rope for work in depths up to 200 fathoms. It consisted of five strands, arranged around a centre of cotton, and each strand consisted of seven steel wires (No. 24 P.W.G.) 0.023 in. in diameter. The diameter of this rope is 0.19 in., and circumference, 0.6 in.; its weight per fathom is 0.33 lb., and breaking strain 10 cwt. It was unfortunately, not made of pre-nosed wire, and has now been in use for three seasons without being kept in any kind of preservative; and although necessarily rusty, its worst fault is that, when in use, it is apt to stain the deck.

In deep water, Captain Sigbee gives the following as safe work:—Time per hundred fathoms, paying out and hauling back, three to five minutes, according to circumstances. He reports a good haul having been made in 800 fathoms in one hour and twenty minutes, including twenty-three minutes for dragging.

My object in furnishing myself with the wire rope was not to dredge, but to be able to anchor in the deepest water to be found on the west coast of Scotland, and thus facilitate the carrying out of physical and chemical observation on the water. In 1877, when I explored a large number of the Scottish lakes and sea lochs, I had found that, in a fresh-water lake, the vertical distribution of temperature is often very different in one place from what it is in another place not many hundred yards distant. The same was also found, though in less degree, in sea-water lakes. It became, therefore, of the utmost importance in investigating the conditions of temperature were really water, to be sure that the observations were really made in one and the same place. It is impossible to keep a vessel stationary in a landlocked bay, with a breeze blowing sufficiently strong to make the vessel drift faster than her lowest rate of steaming. It became, therefore, of the greatest importance to be able to anchor anywhere, and for this purpose the rope above described was furnished. In the season of 1878, I used a kedge anchor of ordinary form, and weighing 84 lbs. It was attached to the wire rope by means of about twelve fathoms of 2½ inch Manilla rope. Often a couple of furnace bars were strapped on to the Manilla at five and ten fathoms from the anchor, with a view to keep a curve on the line. This arrangement was found to work extremely well. Everything was prepared before hand, and when the vessel was in position the anchor was let go, and the wire rope allowed to run rapidly off the reel, the strain on the break at the reel being carefully regulated by means of a spring balance, so that the moment the anchor touched the bottom, the reel stopped. The break was then secured at a known strain, such that as the vessel drifted she would take what rope was required. There was thus no paying down of slack line on the top of the anchor. When it was judged that enough rope had been given, which by strain on the break was increased, which by gradually bringing the weight of the ship on the anchor, steadied it into the ground. When the anchor was found to be holding, it was found in such a way that, if necessary, the vessel could be cast loose, and the work could

proceed. It is of great importance that the rope should be held fast on board in such a way that it can be easily let go; for, if the begins to drag, then the ship gathers way, now the anchor suddenly holds, and it is in danger of veering cable, a very excessive strain is put on the anchor in order to stop the ship's way in a distance. If, however, the reel can be then, by careful working of the break, the ship stopped without any undue strain applied to the rope. The rope passes out of the davits used for "catting" the iron block it is led through another From this block it is led through a balance, to which is attached a spring balance, the line of the steam-winch and the line between the winch and consequently, is always the same; consequently, the fraction of the total strain on the line, shown by the spring balance, is as nearly as possible one-third. In heaving up the anchor, it is necessary to watch the spring balance in order to over-strain the line. The moment the anchor is started out of stiff ground, by quires very careful attention is when the anchor handling of the winch, the strain is kept until the anchor comes away, which is shown by the index of the balance jumping suddenly when the cable is rapidly wound in. It is from the winch by the reel, which is wound

Fig 1.

by hand. In deep water, the covered by a surface layer of no holding power; it is allowed the anchor to sink by this before any great at

the summer of 1878, the anchor used as brought up so many valuable specimens and, especially of those existing below the layer, that I determined before the season to provide myself with an anchor which would not only hold the ship, but retain into which it had fixed itself. It is a Trotman's anchor, with an open frame, a solid bar connecting the two palms. It is placed in a stout canvas bag, into which, sticking to the palm, at the moment of being put out of ground, falls (Fig. 1). This has proved to be a most successful instrument for exploring the bottom of the seas, especially where the object is to collect the mud itself, rather than the shells which live on its surface. Also, as an anchor, it is simple, it is most efficient, being considered as an ordinary kedge-anchor.

The loss of time in stowage, caused by using wire as I have described, will be very apparent, if we consider the amount of it which can be wound on a reel of moderate size. Let the diameter of the core of the reel be 18 inches, and the diameter of the rope 0.2 inch, then if it is wound tightly on such a reel, it will make sixty turns per foot of length. If the diameter of the reel be constructed so that it can be wound on it until the outside of the coil is 28 inches, then the diameter of one turn of wire rope is 28 inches, and the average circumference one-third of this, or 9.3 inches. The number of turns counted in the reel of a radius would be fifty. We should be able to wind on a reel 1 foot long by 2 feet 4 inches in diameter, 3,000 fathoms of wire-dredging rope. The diameter of the cheeks were made, say, 18 inches, then 3,000 fathoms would be easily wound, even without great care in winding. The weight of the line would be 1,000 lbs. It is, however, be advisable, if dredging were attempted at such depths, to graduate the line; for it is quite evident that, with the weight of it out, the part at the surface of the line is to sustain all the strain due to the weight of the line, or 9 cwt. This is the breaking strain when new is 30 cwt. There would be an insufficient margin. The line is often been thrown on the trustworthiness of soundings, as carried out in the simplest way, using a hemp-line and sinker, and keeping the ship as stationary as possible.

The sources of error most frequently met with were, the compressibility of water and the existence of currents, principally under-

standing the fact that liquid suffers compression, its density is consequently, it was asserted, that at great pressure, the density of water will be equal to that of lead, and our sinkers, instead of sinking, will float. Were water compressible to the degree that air is compressible, the density of water might increase at such a rate as to make lead float, supposing the lead to be of the same uncompressible; but, whereas the density of air is doubled by raising the pressure it from that of one atmosphere, or of mercury, to that of two atmospheres, the density of water is only increased by one twenty thousandth, supposing that the compressibility

remains the same at high pressures as at low, it would require a pressure of twenty thousand atmospheres to raise the density of water from one to two, and more than two hundred thousand atmospheres to raise it to the density of lead. One hundred fathoms of sea water exert a pressure of about eighteen atmospheres; and we may assert, with perfect confidence, that the deepest water in the globe is under five thousand fathoms in depth; therefore, even at the greatest possible depths, the density of the water could not be raised by as much as one-twentieth by pressure alone, and the sinking power of lead, which is itself rendered denser by pressure, could not be appreciably affected. This objection to the validity of deep soundings would not have been worth referring to, were it not that it has been admitted by persons of high authority, and has, by consequence, influenced a large number of persons whose convictions are determined by authority alone. Admiral FitzRoy, for instance, in an appendix to his volume on the voyage of the *Beagle*, says, "The depth to which bodies would sink in an ocean several miles deep has not been proved, and there is reason to think that it is much less than people generally imagine," &c. Scoresby, however, twenty years earlier, with his usual acumen, was able to attach its proper value to objections on this ground. He says:—"In sounding at great depths, where the pressure of the water becomes equal to, perhaps, several hundreds weight on every square inch of surface, some persons have imagined that even lead cannot sink, but will be suspended midway in the sea. I have conversed, indeed, with very intelligent persons, who could not be persuaded that any dependence could be placed on soundings obtained at a depth exceeding 300 fathoms. Were water a compressible substance, like air, it would be possible that, under a certain pressure, it might become as heavy as lead, so that lead, or any other ponderous body, could only sink to a certain depth; but water being incompressible, or nearly so, it is clear, however great the pressure may be, that it must be the same downward as upward, on any body suspended; consequently, bodies specifically heavier, will continue to gravitate downward, whatever be the depth or the weight of the column of water above them."

The other objection to the trustworthiness of deep soundings is a real one, though it is often exaggerated. There is no doubt whatever about the existence of surface currents of great extent and velocity in the midst of the ocean; they are observed and measured every day as they form a very important factor in the navigator's daily reckoning. Before deep-sea investigation had received the development which it has now, it was quite uncertain whether these currents (the Gulf-stream, or the equatorial current, for instance) were confined to the superficial layer of water, or extended in all their force to the bottom. No sooner, however, had soundings been attempted in them, than it was found that they were comparatively superficial; but, notwithstanding that they were on the surface, and, therefore, immediately under observation, they caused so much deviation in the direction of the sounding-line, and such uncertainty in the stationariness of the ship, that soundings so obtained were always considered uncertain. It was then said, if we have these

surface currents running from one part of the ocean to another, we must have return currents of some kind, and it is likely that these will be for the most part under-currents; if, now, a surface current, which you have immediately under your eye, gives you so much trouble, how much more will this be the case with an under-current of whose strength, and direction, and depth, you are ignorant?

It must be admitted that when we do meet with currents of the kind imagined, soundings taken in them, whether with wire or hemp line, are very much less to be relied on than those taken in manifestly quiet waters; but, on the other hand, the existence and extent of under-currents has been very much exaggerated. By far the larger portion of the ocean is, for sounding purposes, practically still water. The surface currents of any importance are easily recognised, and so also are the under-currents. Just as a physician can, by bringing his experience to bear on the sounds transmitted to him through the stethoscope, divine what is taking place inside the body of his patient, so the experienced seaman can, by observing the behaviour of his sounding-line, form a fair diagnosis of what is taking place in the depths of the sea. When the sinker passes into a belt of under current, the fact is very soon apparent, and calls for the greatest care in the manœuvring of the ship. Even with the greatest possible care, however, soundings, taken under such circumstances, would always be considered to be of doubtful value. If no bottom is brought up, they should be looked on as very doubtful, and even discarded; if bottom is brought up, then we know that the depth is not greater than the line used, and a correction, suggested by observation and experience, may be applied, which will bring the depth very near the truth. Although, as we have said, by far the greater part of the ocean may be looked on as still water, and, therefore, favourable for investigation with the sounding-line, it is, nevertheless, of great importance to obtain accurate measurements of the depth of water under well marked currents.

It is evident that this cannot be satisfactorily done by the sounding-line alone, and it early occurred to those who thought on the subject that the method which promised most success was that which should give the depth in terms of the height of the column of water; in other words, the barometrical measurement of altitudes was extended from the land to the sea. Many and various instruments have been suggested and used for the purpose. They are all constructed with a view to record the amount of compression produced on a given mass of a certain elastic substance. From the known law regulating the variation in volume of the substance with variation in the pressure, the maximum pressure to which the instrument has been exposed can be deduced, and from the known density of the water, the height of the column of it, which would produce this pressure, can be calculated, and this height is the depth to which the instrument has been sunk. Many different substances have been used for this purpose, and foremost amongst them air, on account of its great compressibility. For deep work, however, this was quickly found to be a great disadvantage, so great, in fact, that it has

never been satisfactorily used at depths.

The compressibility of water was first demonstrated in 1762 by John Canton, and, fifty years later, extending Canton's original observations on pressures, Perkins sank his instrument to great depths in the North Atlantic Ocean from America to this country. They were glass tubes, sealed at one end with water, and inverted in a cup of water. The tube was a steel index which rose and was retained by a spring at the top. It could be drawn down to any depth, and the instrument so reset by means of a screw to the outside of the tube. Enclosed in the tube were results so obtained, Perkins constructed an apparatus, in which he could expose the instrument to enormous pressures, which were directly by the weight which it supported. He, at the same time, used these instruments, or piezometers, for determining great depths. The experiment was repeated in 1848, by Aimé, and many valuable researches in the subject have since been made, and by the United States Coast Survey. The same idea occurred to me of my appointment to the *Challenger*, it is one of those ideas which need themselves to any one who seriously studies the subject. The form of piezometer to me to be best suited for the purpose, essentially that of Perkins, with convenient practical modifications.

FIG. 2.

instruments, I used generally distilled water, or an equivalent. The bulb and stem of the instrument were so portioned that, for a depth of one fathom, the apparent contraction of the water was the length of ten millimetres. Some more, and others less, delicate than in using water, or weak salt solution, was that, as the temperature of these liquids was not 1

that obtaining in the great mass of deep oceanic water, a considerable inaccuracy in the determination of the temperature of the water would make a sensible difference in the apparent volume of liquid, and therefore would not sensibly vitiate depth determination so obtained. Unfortunately, the vicinity of the temperature of minimum density exercises an influence on the compressibility, which counterbalances its advantages from a thermal point of view. A strong solution would probably be better. Were the temperature at the bottom of the ocean subject to variations, the use of distilled water would be inadmissible, but over large areas, its variations are confined to fractions of a degree. Hence, irregularities in the depths given by the thermometer, and due to this cause, are small though absolutely to be neglected. I am engaged, at present, in experiments to determine what is the best liquid to use for this purpose.

Another method of measuring the pressure, and through it the depth of the sea, is by means of an instrument much resembling, in principle, the aneroid barometer. Its simplest form is that usually given to a mercurial thermometer. When the pressure on the outside of the instrument is increased, the bulb experiences a tendency to collapse. It yields wherever its walls are weakest, and if the pressure is kept within the necessary limits, a flattening is produced, which reduces the internal volume of the bulb, and forces the mercury into the stem; if an index is fitted in the stem, its position will indicate that of the column of the mercury at the moment of test compression. Inventions on this principle have been patented over and over again in the space of the last twenty or thirty years.

A chief objection to the instrument is that, in use, it is always filled with mercury. Over the water part of the ocean, the temperature of the water falls as the depth increases. Hence, the mercury will be continually retreating, owing to its contraction due to fall of temperature, while it is pushed forward by the mechanical collapse of the bulb. Until these two effects compensate each other, there can be no movement of the index, and therefore, no indication of the depth. In regions of tolerably uniform temperature, as in the tropics, it ought to do well. Two instruments of this kind were sent to the *Challenger* by Massey, but they only reached her at the last before her return to England. They were used twice, and did not on those occasions give satisfactory results. Sir William Thomson within the last year, patented an instrument on the same principle, where the collapsible globe is a very flat brass tube.

Very analogous to sounding in a current is the method of sounding from a vessel in motion. I have already described the ordinary operation of heaving the hand-lead, by means of which the depth up to twelve or fifteen fathoms can be ascertained under ordinary circumstances. For deep water, however, and with vessels running at high speed now common amongst mail steamers, a self-adjusting apparatus is an essential. Within the last few years, the commonest of apparatus of the kind was Massey's sounding machine. In sinking, the friction of the passing water caused a screw fan to rotate, and the

number of its rotations was recorded on dials in much the same way as the distance run by a ship is recorded by Massey's patent log. The form of this instrument, requiring, as it does, a system of multiplying wheels, causes it to offer considerable resistance when being hauled on board again; it is, therefore, not suitable, except for vessels going at a moderate speed. Further, if we look to the principle of the instrument, we see that what it in fact registers is the distance travelled by the instrument between the surface and the bottom. If it has been allowed to sink freely, then this distance will be equal to the depth of the water. But if, while sinking, it were exposed to a certain amount of drag, through strain on the sounding-line, it would tend to sink sideways, which would put the screw fan to a disadvantage, and vitiate the determination of depth. Practically, this objection has little force, because, in a ship where it is thought proper to execute soundings of the kind, there will be no difficulty in seeing that the sounding-line runs out freely.

In arranging for taking soundings from quickly moving ships, it is important to have not only an instrument which will be dependent only on the true depth of the water for its indications, but also such mechanical appliances as will enable the operation to be carried out safely and expeditiously. To Sir William Thomson is due the credit of having furnished the practical solution of this as of many other problems. His original apparatus for registering the depths was a glass tube, sealed at one end, and coated internally with a chemical preparation (chromate of silver) the colour of which was changed by the action of sea water. As the tube, with its included air, sank, the volume of the air diminished, and the sea water penetrated further and further into the tube, until the bottom was reached. On rising to the surface again, the elasticity of the air reasserted itself, and eliminated the water which had entered. The height to which the water had risen was given by the extent to which the internal coating of the tube was altered. The indications of this instrument were always very good, and the practical objection to it lies in the fact that a tube only serves for one sounding, and that, therefore, a number of these have to be carried.

In June, 1879, I patented an instrument, in which the degree of compression to which an enclosed mass of air had been subjected, was measured by the water which had gained admittance to the instrument.

As I now use it, the instrument is represented in Fig. 3. It consists of a glass tube open at both ends, but capable of being closed by a stopper or other means. At some part of the tube a spout is introduced, and the tube is bent over through two right-angles immediately above it. When the instrument is to be used, the end is closed, and the line let go; when bottom has been reached, it is brought up again, and we find that a certain amount of water has lodged in the lower part of the tube. It is evident that, as the instrument descends and the air in it is compressed, the water forces its way in through an orifice, and past the spout. This spout is so formed that it delivers the water against the walls of the tube, down which it runs, and collects at the bottom. When the motion of ascent begins, the air, by its elasticity, tends to re-

cover its original volume, and expands in the direction of greatest freedom. Now, all the water which has entered has collected below the spout, consequently, in re-expanding, this water will be left undisturbed.

Assuming that the volume of the mass of air in the instrument varies inversely with the pressure to which it is subjected, we require, in order to be

FIG. 3.

FIG. 4.

able to construct a scale for our instrument, and so to interpret its results, to know the total volume of the tube, the volume of the part which I call the vestibule, the dimensions and volume of the narrow tube, and of the wide one. Then, if  $V$  be the total volume of the tube,

and  $v$  that of the vestibule, the amount which gains admittance when the pressure is from one to  $p$  atmospheres is—

$$v' = V - \frac{V}{p} - v$$

$$= V \frac{p-1}{p} - v$$

The methods by which a correct scale can be easily applied to any instrument, whether engraved either on the glass or on the metal, on both, are details of practical instrument-making which need not detain us.

Convenient dimensions for such an instrument are—Total volume, twenty metres; volume of vestibule, one metre; length, forty to fifty centimetres, hauling in the sounding line to a ship, the machine comes to the surface a considerable distance astern of the ship, to be towed through the wake, need dipping under the seas. Each dip which constitutes an independent, though short, haul, and the volume of the vestibule proportioned to the volume of the instrument during such immersions no water enters the spout. When the instrument has been used it is at once available for a fresh sounding, necessary to remove the stopper, the water runs out, and then replace the stopper. Fig. 4 represents an instrument modified so that it can be used either for great or for small depths, according as either end is closed.\*

Sir William Thomson, in his latest patent (February, 1880), recommends three instruments, constructed some lines of the above instrument, but of sizes so apportioned that each shall be sensitive at certain depths. He also recommends the use of the "elastic bottle gauge" above, combined with the triple air gauge, to give measurements of from 300 or 400 fathoms.

It may reasonably be doubted if it is a matter of any importance to the practical man to obtain a positive sounding in 300 or 400 fathoms of water, either with or without stopper, and to do so without checking her way is a very serious undertaking. The vessel will not sink at a greater rate than 10 fathoms per minute, or four minutes to sink a hundred fathoms, and during four minutes going not more than 10 knots per hour, will have advanced by 660 fathoms, so that, when the vessel has been struck, there will be at least 660 fathoms of wire, which, even with stopper, will be reeled in under a quarter of an hour. The second and more mechanical

\* After the above was written, my attention was called to an instrument, the principle, though differing greatly in the details, invented by Eriksen, and used successfully on her Majesty's ships. It is described and figured in the *Naval Magazine* for 1886, and is reported on very favorably by Sir William Thomson, who was also the inventor, and they obtained successful soundings of 80 fathoms, while going at a rate of six knots per hour, with the sounding machine. Eriksen brought on board the *Albatross* for use, in place of sounding line. Captain Meade reported that it had been constantly and successfully used on the *Albatross*, when engaged in the survey of the North Atlantic in H.M.S. *Albatross*, in 1846, and that it had a great success.

of deep sounding while under way, has been used by Sir William in an elegant and simple form. His navigational wire sounding line is that is requisite in the smallest compass. For my own work, I have made slight modifications in the details. It consists of a solid hard wood core, thoroughly painted, and surrounded with a brass sheath of which the wire is wound, one of which, on each side, is a break pulley. A soft hemp line is used for the breaks, which is used purely as a friction break is at one end to a spring balance, by means of which any definite pressure can be put on the wire. The other is used as a locking break, that is, it is taken one complete turn round this pulley, so that the direction in which it revolves when the weight is running out. When the weight has arrived to strike the bottom, this break is tightened, which instantly locks the reel. The handles are manned, the breaks thrown, and the wire wound in. I depart, also, from Sir Thomson's practice in using galvanised in right steel wire. In order to allow for any weakening effect of the galvanising, I use a wire of a size larger. In a small vessel like the *Albatross*, I found it very inconvenient working on the taffrail. I have it now well in, and the wire leads out through a metal sheath specially constructed for the purpose, and to the flag pole, as high up as a man can reach. In this way the work is carried out without difficulty. The galvanising is a perfect protection to the wire, and all work with tanks and solutions is spared. Instead of having a hook at the end of the wire, I reeve the wire through a piece of  $\frac{1}{4}$ -inch block-tape, about 15 inches long, and then bend and splice up the end of the wire so as to form a loop, to which the stray line for sinker and sounding machine can be attached.

In the U.S. Coast Survey Report for 1857, a ingenious sounding instrument is described by Mr. Hunt. The instrument consists of an air bag, made of flexible material, with a flexible tube attached to it. This bag, being filled with air, is sunk to the bottom (in a moderate depth of water), preferably by a heavy grating surrounds and protects it. The other end of the flexible tube is connected with a Bourdon's gauge in the ship or boat. If, now, this instrument is towed over the bottom, and the pressure observed on board, an exact profile of the bottom is given. I am not aware that this instrument has ever been much used for harbour surveying, which it was intended—and it is not difficult to see where practical difficulties would be likely to occur; it has, however, been used with success as a tide-gauge, and it is clear that, for this purpose, it possesses many advantages. It being securely anchored under water, it is connected by a pipe of any length with the tide-gauge, or a recording instrument under

with the ordinary thermometer, and it was used in one or two ways; either it was sunk itself to the desired depth, and was so enveloped and protected by badly conducting material, that in bringing it up again through the layers of water of different temperature it had not time to alter its own temperature, or a quantity of the water at the desired depth was enclosed in a bucket of suitable construction, and brought to the surface, and then immediately tested with the thermometer. Many very excellent and trustworthy observations exist, which have been made in one of these ways. Our first knowledge of the temperature of the deep water of fresh-water lakes was obtained from the observations of De Saussure, on the lakes of Switzerland, made with a thermometer, so padded and protected that it could be drawn up through 1,000 feet of water, of any temperature likely to be found in Nature, without sensibly altering its temperature.

The self-acting bucket, or sea-gauge, was used at an earlier date in the determination of the temperature of the deep water of the ocean. The accuracy of the results obtained by this method depends greatly on the skill of the observer. In the case of De Saussure, and of Fischer and Brunner, the results are clearly to be relied on implicitly. In the experiments with the sea-bucket, also, excellent results have been obtained. The results obtained by both methods of experimenting will be the more accurate the more uniform the temperature of the water. The temperature, especially of the bottom water, has also frequently been determined by bringing up a quantity of the mud, and taking its temperature when it arrives on board. This method also gives very satisfactory results when a considerable quantity of mud is at disposal.

*Self-Registering Thermometers.*—By far the greatest number of observations has been made with self-registering thermometers of one form or another. The first self-registering thermometer was made by Cavendish. He constructed both a maximum and minimum thermometer, and they were of the kind called by the French *diversement* out-flow thermometers. In fact, his maximum thermometer is in every particular identical with that known in France as Walferdin's; his minimum is on the same principle, but has a U-formed stem instead of a straight one. The disadvantages of this form of thermometer are two—namely, the indications are not continuous, but by jerks, depending on the size of the mercury drops, and they require to be constantly set, the maximum at a higher, and the minimum at a lower temperature than the one to be observed; they also require constant comparison with a standard. They are, therefore, not suitable for use where many observations have to be made expeditiously.

In the year 1782, Six published a description of the combined maximum and minimum thermometer which bears his name, and which has since continued to assert its place among meteorological instruments as perhaps the best self-registering thermometer. The instrument is too well-known to require particular description. It may, however, be noted that Six himself did not use a hair for a spring to keep his indices from falling down, but a fine glass thread soldered to the top of the index, and sticking up in a direction very slightly inclined to that of the length of the index, so that it pressed

the purpose of observing the temperature of the water below the surface in lakes and seas, the use of thermometers have been used, ordinary thermometers and self-registering. The earliest observations were made

gently against the sides of the tube. The advantage of the glass over the hair is that it does not lose its elasticity; but, on the other hand, the index takes up more room, and requires a thermometer with a larger stem.

Maximum and minimum thermometers, such as Cavendish's and Six's, when used for deep-sea exploration, show only the maximum and minimum temperatures to which they have been exposed in any one excursion, and a single observation with such a thermometer does not give us with certainty the temperature of the water at the depth to which it has been sunk. Hence, if we had a right to assume that the temperature of a sea or lake might vary in any conceivable way with the depth, these instruments would be valueless. We have, however, no right to make this assumption; we know, on the contrary, that in all seas whose surface is not exposed to a freezing temperature, the temperature of the water will, as a rule, diminish as the depth increases, that, therefore, the minimum temperature, as shown by the self-registering thermometer, will, in fact be the temperature at the greatest depth attained by this thermometer. Hence, in such cases, this instrument is to be relied on, and more especially when series of temperatures are taken—that is, when the temperatures at different depths in the same locality are taken, so that the evidence of the decrease of temperature with the increase of depth, is rendered as strong as possible. In order to render an account of the state of any lake or sea, as regards temperature, it is absolutely necessary to have such serial observations; hence, for such investigations, the maximum and minimum thermometer is not only trustworthy, but a most valuable and, indeed, indispensable instrument, for it has the great advantage that, as it is in the strictest sense self-registering, any number can be attached to the same line, and so, at one haul, the temperature can be observed at a number of different depths.

For isolated observations, the thermometers just described are not so satisfactory, and a very great amount of ingenuity has been displayed in the invention of machines for registering the actual temperature of the water at any depth, independently of that of the water above it.

None of the instruments devised for this purpose have been strictly self-registering; they have all required some assistance from the observer, who, by various forms of mechanical appliance, brings about a catastrophe which leaves its mark on the condition of the instrument. It is obvious that any control which an observer may have over an instrument separated from him by, it may be, three or four miles of cord, is very limited, and is, in fact, confined to his ability to move it towards or from him. By a simple mechanical contrivance, this longitudinal motion may be made to produce one of rotation, and, in fact, the assistance afforded by the observer to the thermometer, to enable it to register its own temperature, consists in his turning it either upside down or through a whole circle when it has reached the desired depth. The first observer who made use of this device was Aimé. His working arrangement is described in "Ann. Chim. Phys.," 1843 [3], vii., p. 497. It is worked by a weight, which is allowed to slip down the line, and which then sets free the apparatus.

His *thermomètre à bascule*, along with a number of ingenious modifications of existing forms described in the same journal, 1845 [3], xv., p. 1. It was unfortunately only after he was obliged to leave the Mediterranean, which had been the scene of his labours, that he invented the very elegant combination of thermometers by which he enabled to ascertain the temperature at any depth, no matter what the intervening distribution might be. It is described in the memoir just cited consists of two outflow thermometers, so constructed that the one of them registers the successive rises of temperature, and the other the successive falls of temperature, to which it is exposed on any excursion. When they have reached the required depth, they are inverted, and on their return back to the surface they register, as above described, the rises and falls of temperature to which they are exposed. If  $r$  be the sum of the rises of temperature, and  $f$  the sum of the falls, the temperature at the depth where they were inverted will be  $a = s + r - f$ .

If they are allowed to register on the way down and then inverted at the greatest depth, so as to register on the way up, the effect will be precisely the same, though the functions of the two thermometers will be reversed.

Beautiful and ingenious as Aimé's thermometers are, they have the disadvantages common to outflow thermometers; they are neither so strong enough nor handy enough for work involving many observations. The inverting thermometer patented by Messrs. Negretti and Zambra, and the conditions required of a thermometer for isolated observations as completely as can be hoped for. It is a mercurial thermometer; the bore of the stem is contracted to the smallest possible diameter at a point about an inch above the neck of the bulb. As long as the thermometer is standing vertically, stem uppermost, the mercury is continuous in stem and bulb; but if it be inverted, the mercury parts at the contraction point in the stem falling down into the bulb. The stem is graduated from the point to the bulb, and the temperature, at the moment of inversion, is read off by the height of the mercury in the end of the stem. This thermometer is in two varieties, the one with a U-formed stem which requires to be turned completely over. The turning arrangement for the latter instrument is a somewhat elaborate and expensive one, but it answers its purpose. The inverting arrangement, supplied with the half-turn thermometer, is somewhat clumsy and unsatisfactory. The half-turn instrument, when fitted with a screw-inverting arrangement, is to be preferred to others in all work at moderate depths.

*Sources of Error in the Indications of Thermometers.*—When an ordinary thermometer is protected by badly-conducting envelopes, it is obviously exposed to alteration of temperature by being pulled through warmer or colder water on its way to the surface. Whether any error is likely to result from this cause, and how determined in each particular case by exposure. The more perfectly it resists change of temperature the longer it will take to assume the temperature of the water. De Saussure left his thermometer down for twelve or fourteen hours for each observation, so that this method is now seldom

, also, the method which depends on up a sample of water in a vessel fitted up, and taking its temperature with a thermometer, when it reaches the surface is discontinued; for although it does more time than would be necessary for a thermometer and bringing it up, is able to bring up water from great depths in climates without sensible change of tem-

perature of outflow thermometers, the delicacy of the instrument is limited by the size of the drops. In the inverting thermometers of Zambra an error may arise from the change of volume of the mercury in the stem, at the temperature at which it was inverted and at which it is read. In an extreme case this amount to as much as  $0.4^{\circ}\text{F.}$ ; it can, however, be allowed for.

In the instrument there is a possible error arising from the indices, in consequence of which they are apt to be shaken out of their places during the use of the line. Errors from this source are avoided to a great extent by attaching the thermometer to the line, by means of an elastic or rubber tube.

Self-registering instruments are liable to errors from the effects of pressure. The pressure on the thermometer is never greater than that of the atmosphere when it is sealed up. It may, however, be exposed outside to a pressure of 500 atmospheres. The effect of this difference of pressure on the outside and inside of the glass is to make it tend to collapse. The bulb of the thermometer is squeezed, and its volume, consequently, diminished. The liquid which it contains is thereby forced into the stem, and its volume is greater than it would have been had there been no excess of pressure on the outside of the instrument. The temperature of the liquid is measured by the apparent volume of the liquid which it contains; hence the effect of pressure is to raise the observed temperature above the true temperature. Parrot and Lenz, in 1832, made a series of experiments on the effect of pressure on thermometers. They experimented at pressures up to 100 atmospheres, and observed the difference between the apparent and the true temperatures of as much as  $20^{\circ}\text{C.}$  They found that the same instrument the compression was proportional to the pressure. They used a thermometer as a manometer. After this date it was attempted some kind of protection for self-registering thermometers.

Thermometers with straight stems, such as Walferdin's, were sealed up in glass tubes, and so they were protected. Those whose stems were not sealed up were enclosed in metal cases closed with a screw. This form of protection never answered, as it was impossible to screw on the cover so as to make the water, under the great pressures met with at considerable depth, would not find its way under the cover not to have to abandon the use of thermometers of the convenient form of Six's, the protection of the bulb only was hit upon. It appears that the first thermometer of this kind was used by Captain Pullen, on board the *Cyclops*. The effect of pressure on the thermometer was quite insignificant, and under ordinary circumstances, insensible. For, in nearly all

cases where the surface temperature is over  $40^{\circ}\text{Fahr.}$ , the temperature of the water diminished as the depth increases, and, therefore, it is the minimum leg which is used, and the effective part of it is that filled with spirit, which may have a length of, at most, three inches. The effect of pressure in diminishing the volume of a short piece of thermometer tubing must certainly be very small, but its actual value can only be determined by removing the bulb, and taking the piece of the stem between the mercury and the neck of the bulb as the bulb of a new thermometer, and determining experimentally the effect of pressure on it. An approximation to the effect may be made by exposing the thermometer to various high pressures, at known temperatures, and observing the rise of the maximum index, then removing the bulb, and calibrating the stem. Knowing, then, the ratio of the volume of this part of the minimum leg, filled with spirit to the whole volume, from the bulb to the maximum index, it may be assumed that the compression will be in the same ratio. And this value will probably be greater than the real one, for the compression of the water produces of itself a certain rise of temperature, and, consequently, rises the maximum index. This can, however, be estimated, either by a comparison with a completely protected thermometer, or by bringing the minimum index also home on the mercury before raising the pressure. If, then, there has been a rise of temperature caused by compression, there will be a corresponding lowering of temperature on relieving the pressure. If the compression apparatus be allowed to stand after the pressure is up, until it has dissipated the heat evolved by the compression, the relief of pressure will cause a corresponding absorption of heat, which will show itself in the position of the minimum index. Some experiments which I have made in this direction show a lowering of temperature of  $0.3^{\circ}\text{Fahr.}$ , for the relief of a pressure of  $2\frac{1}{2}$  tons per square inch, the whole rise of the maximum index having been  $1.8^{\circ}\text{Fahr.}$  We may, I think, be quite certain that when the minimum leg is the one used, and the temperature low, the error caused by the effect of pressure on the stem is inappreciable. Cavendish, who invented the self-registering thermometer, foresaw also the most important of the uses to which it could be applied. Thus he suggests that the higher regions of the atmosphere might be investigated by attaching it to a kite—balloons not having been invented. With regard to deep sea explorations, he says:—

"If instruments of the nature above described were to be used for finding the temperature of the sea at great depths, some alteration would be necessary in the construction of them, principally on account of the great pressure of the water, the ill effect of which can, I believe, be prevented no other way than by leaving the tube open."

This was written in 1757, and it was not till 1762, as already stated, that Canton proved that liquids are compressible. Cavendish, therefore, hoped that as the pressure would not produce distortion of the glass when the tube was open, it would have no visible effect on the apparent volume of the liquid. The device of leaving his thermometer open at the end was adopted by Aimé in some of his experiments. The effect of pressure on the apparent volume of the

Liquid being determined independently, and a correction applied accordingly. I devised and constructed a mercurial thermometer, or piezometer (Fig. 5) on the same principle, but my object in admitting the water pressure to the inside of the instrument, was to utilise it in shifting the scale of the thermometer as the depths changed. The thing registered in such instruments is always the apparent volume of the liquid, and this varies with the temperature and the pressure. Hence the indications will represent the sum of the effects of the change of temperature and of pressure. If from any independent source we know either of these, we can determine the other. In a sea of uniform temperature throughout its depth, the apparent volume of the liquid would diminish as the pressure increased, and if the temperature increased with the depth, the apparent volume of the liquid would diminish at a slower rate; but it would be always possible to determine the true temperature as long as it did not increase at so great a rate as to dilate the liquid more than it was compressed by the increasing pressure. For the investigation of

FIG. 5.

seas such as the Mediterranean, this form of instrument is most valuable. The method of determining accurately both depth and temperature from the combined reading of a mercury and a water piezometer is explained in the paper communicated to the Chemical Society.\*

In the great majority of cases, the most convenient instrument to use is the form of Six's thermometer with protected bulb known as the Miller-Casella thermometer, with the following additions and improvements, which Mr. Casella has applied to them at my suggestion:—The size of the instrument is increased so that the degrees are wider apart, a degree Fahrenheit on the minimum leg occupying about three millimetres of its length. Besides the scale of degrees which is attached in enamelled slips to the vulcanite at the sides of the stem, there is an arbitrary (millimetre) scale etched on the stem itself. The valves of the division of this scale are ascertained by a careful comparison with a standard thermometer. It is thus possible to

read with certainty to a quarter of or a twelfth of a degree Fahrenheit. to the scale not being rigidly attached to the instrument, and to the difficulty of determining the height of the index by reference to the side of, instead of over it, are eliminated by having the ordinary scale at the top of the instrument can be used independent of any arbitrary scale, and, even where the scale is principally relied on, the scale enables the observer to know very nearly the true temperature at the moment of observation, without reference to tables, and on every occasion the reading is free from chance of errors from misreading introduced. The maximum leg, which is used, is of larger bore than the minimum degrees, therefore, are closer, and the index of the instrument may rise as high as the maximum without the index entering the minimum. This is a detail of considerable practical importance, for it is impossible always to use thermometers, when on deck, from the heat of the sun, which would speedily destroy the maximum side of the thermometer were as limited as that of the minimum.

It will be seen, from what has been said, that there is no one instrument which fulfils all the conditions required of a perfect thermometer. It is necessary, therefore, for the investigator to use his judgment in selecting the instrument best suited for the case before him. In order to be prepared for all the possibly occurring cases, he should have with him thermometers of (a) the Miller-Casella with improvements just described; (b) the piezometer, (c) the Negretti and Zambra thermometer. It is well to have at least one of each class (a), as any number of thermometers attached to the line at different depths would save much time. In my own practice I use four or five at a time. It is not to exceed this number, as the line would be too heavy. The distribution of temperature in lakes and seas of warm and temperate climates is the most generally useful in a thorough investigation by means of observations is intended. In the most frequent and frequently occurring case of a calm sea, containing a large mass of water with no variations of temperature within a few fathoms, this instrument, it must be required, a mercury piezometer (b), which possesses the advantage that the position of the thermometer shifts along the stem according to the depth. Also, any number of thermometers may be used at the same time at different depths along the same line. The inverting thermometer of Negretti and Zambra (c) is the instrument suitable for isolated observations. It has very great use for supplementing the observations with the other thermometers, especially in the case of sea lochs where the temperature distribution is disturbed by the imperfect mixture of water.

For the successful and expeditious investigation of deep-sea temperature observation the investigator should be furnished with im-

\* "Journal of Chemical Society," October, 1878. The blocks of Figs. 3, 5, 6 have been kindly lent by the Council of the Chemical Society.

nometer for the bulk of the work, and piezometer and the investing thermometer cases. All the thermometers, of type, should be carefully compared to standard, and the results stated in scale.

Determination of the specific gravity of is necessary to have an instrument of delicacy, which can be used in all rather at sea. The specific gravity of ordinarily determined in one of two with the specific gravity bottle, when of a known volume of the liquid is served, or with the hydrometer, when of a known weight is observed. A modification of the hydrometer, namely, vity bulbs, has long been in use for uses, and they have been used by Dr. and others for sea-work. The only objection to their employment, in work of purely interest, is that each bulb, being in effect a hydrometer, has to be separately tested for weight and volume, and for change of density with changes of temperature. A large number of bulbs which is necessary involves an enormous amount of labour without corresponding advantage. Sets of stems, graduated so as to include all varieties naturally occurring in the sea, is used. When each hydrometer has been of the requisite delicacy, and of workmanship, it is necessary to have a set of stems; and the same objection obtains of the bulbs. For the work of the instrument of suitable size and properly constructed. Its stem carried an ale (millimetres), and was very carefully the weight of the whole instrument fully determined, and also the dilatation of the body. The instrument was entirely by a contrivance similar to that used in hydrometer, weights could be placed in the sub-cavity of the stem. By this means usefulness of one hydrometer can be beyond the limits occurring naturally

When independently this work, I have some of the details of the instrument, never, in any way altering its general form. In the *Challenger* instrument, the body, containing about four diameters in the heavier form it is a sphere of the same volume, this materially reducing the weight of the instrument. Instead of a small brass weights to be laid on it, the weights are brass cylinders, closed at one end, and a flange at the open end with others of flat rings, which can be slipped on the cylindrical weights, and then rest on the stem. These are small mechanical details, which, greatly affect the handiness of the instrument, and they are therefore of importance. The following is a description of the instrument used for the whole of the work during the cruise of the *Challenger*. The instrument carries a millimetre scale 10 centimetres long, has an outside diameter of about 3 centimetres, the external volume of the divided body is 0.8607 cubic centimetre; the mean volume of the body is 180.15 cubic centimetres,

and the weight of the glass instrument is 160.0405 grammes. With this volume and weight, it floats in distilled water of 16° C. at about the lowest division (100) of the scale. In order to make it serviceable for heavier waters, a small brass table is made to rest on the top of the stem, of such a weight that it depresses the instrument in distilled water of 16° C. to about the topmost division (0) of the scale. By means of a series of six weights, multiples by 1, 2, 3, 4, 5, and 6, of the weight of the table, specific gravities between 1.00000 and 1.03400 can be observed. It is not necessary that these weights should be accurate multiples of the weight of the table; it is sufficient if they approach it within a centigramme, and their actual weight be known with accuracy. The weights of the table and weights in actual use are:—

Weight of table .....	0.8360 grammes.
Weight of weight No. I.	0.8560 "
" " II.	1.6010 "
" " III.	2.4225 "
" " IV.	3.1245 "
" " V.	4.0710 "
" " VI.	4.8245 "

For oceanic waters, the hydrometer is always used with the table, and either No. IV. or No. V. weight.

When the mechanical part of the construction of the instrument was finished, with the exception of the closing of the top of the stem (which, instead, was widened into a funnel-shape, large enough to receive the ordinary decigramme weights), the calibration of the stem was effected by loading the stem with successive weights, and observing the consequent depressions in distilled water of known temperature. This done, the top was sealed up, and the instrument carefully weighed. The expansion of the body with temperature was determined in a similar manner, by reading the instrument in distilled water of various temperatures. The co-efficient of expansion of the glass was then found to be 0.000029 per degree Centigrade.

For using this instrument at sea, about 900 cubic centimetres of sea-water are taken, and the containing cylinder placed on a swinging table, in a position as near the centre of the ship as possible. The observation with the hydrometer, loaded with the necessary table and weight, is then effected in the ordinary way, the accuracy of the readings being but little affected by rolling; pitching, however, is found to have a distinctly disturbing effect; and when it is in any way violent, it is advisable to store the specimen of water till the weather improves.

The temperature of the water at the time of observation is determined by one of Geissler's "Normal" or standard thermometers, graduated into tenths of a degree Centigrade; and it is essential for the accuracy of the results that the water, during the observations of the hydrometer, should be sensibly at the same temperature as the atmosphere, otherwise the changing temperature of the water makes the readings of both the hydrometer and the thermometer uncertain. At low temperature (below 10° or 12° C.) a tenth of a degree makes no sensible difference in the resulting specific gravity; but, at the high temperatures always found at the surface of tropical seas, rising sometimes to 30° C., the same difference of tempera-

ture may make a difference of three to four in the resulting specific gravity.

Having obtained the specific gravity of the water in question, at a temperature which depends upon that of the air at the time, it is necessary, in order that the results may be comparable, to reduce them to their values at one common temperature. For this purpose a knowledge of the expansion of sea-water with temperature is necessary.

This had been determined with sufficient accuracy for low temperatures by Despretz and others; but as the temperatures at which specific gravity observations are usually made are comparatively high, their results were of but little use, directed as they were chiefly to the determination of the freezing and maximum density points. When the late Captain Maury was developing his theory of oceanic circulation, owing to difference of density of the water in its different parts, he found the want of information on this important subject. At his request the late Professor Hubbard, of the National Observatory, United States, instituted a series of experiments, from which he was enabled to lay down a curve of the volumes of sea-water at all temperatures, from considerably below the freezing point to much above what obtains even in the hottest seas. The results are published in Maury's "Sailing Directions," 1858, vol. i., p. 237, and have evidently been carried out with great care. The composition of different oceanic waters varies, even in extreme cases, within such close limits, that the law of thermal expansions is sensibly the same for all of them; of this, Hubbard's experiments afford satisfactory proof. In the table which gives the results of all his experiments, he takes the volume of water at 60° Fahr. as his unit. In order to avoid much useless calculation, I have been in the habit of reducing my results to the same temperature (15·56° C.), while, for a like reason, I have retained the specific gravity of distilled water at 4° C. as the unit. The choice of a common temperature, to which the results should be reduced, and of a unit of specific gravities, is a purely conventional matter; and in choosing the above-mentioned ones, in the first instance, I was moved solely by a desire to save calculation. For every water, however, there is one temperature to which it would be natural to reduce its specific gravity, namely, the temperature which the water had when in its place in the ocean; and in this sense all my results during the cruise have been reduced. Hubbard's table of the change of volume of a mass of sea-water, with change of temperature, enables us very easily to reduce any observed specific gravity from the temperature of observation to any other temperature, say 15·56° C.

*Collection of Samples of Water.*—The water from the bottom was usually collected in the so-called "dip" water-bottle, which has been described by Professor Jacobson. Water from intermediate depths is obtained in an instrument represented in section in Fig. 6. It is made entirely of brass, which, however, might advantageously be nickel-plated. It consists of a cylinder, A, terminated at both ends by similar stop-cocks, B B, which are connected by the rod, C. This rod carries, near its upper extremity, a piece of stout sheet brass, D, 10 centimetres long by 15 broad, soldered to the casting, E, which is movable about the axis, F. The function of this part of the apparatus will be

more easily explained by describing the operations necessary when collecting water.

When intermediate water is to be of water-bottle is firmly attached to the line, which carries at its end usually 1 cwt. lead; the stop-cocks are then op-

FIG. 6.

them, with the rod, C, the position in the figure. The line is then lowered by hand, until the water-bottle is at surface, when it is let go, and allowed to run out without a check its passage downwards, the water comes through it, being considerably assisted by the conical end pieces, K, K. When the required depth has been reached, the line is checked by the same mark, and finally hauled in by a donkey-engine. When the line is hauled in, first, the flap D falls down into a position, when it is caught by the m of brass, F, which moves round an axis supported on the side opposite to E, by which rests on the spiral spring, H. On hauling past D, when thus in a horizontal position, it exercises a sufficient pressure upon the stop-cocks, B, B. When the speed of the bottle is hauled through the water the pressure on D becomes so great, that it overcomes the tension of the spring, H, and the catch, F, when the rest of the journey is performed with the flap, D, horizontal and therefore offering the least resistance to the water. The object of hauling in only a couple of fathoms, before letting the line go again, is to prevent the stop-cocks being closed. For, supposing the first hauling in they were not closed by letting the instrument descend in water, the flap, D, sets itself again, and on hauling in, it shuts down the stop-cocks, but not before but partially closed; or, if

closed before, it only shuts them the tighter. When the water-bottle has been brought up, it is only necessary to substitute for the lowermost stem funnel a small nozzle, when the water may be tapped into any vessel destined to receive it. This done, the bottle may be at once lowered to any other required depth, much time being spared by not having to detach it each time. At the upper end of the bottle a small spring safety valve, *V*, is introduced, in order that the considerably denser water from below may be able to make room itself as the surface is approached. In order that the instrument may properly do its work, it is evident that, first, the stop-cocks should be such that the weight attached to their levers be not sufficient to close them; and, secondly, the spring, *U*, should be so strong as to ensure the closing of the cocks before it itself gives way. These conditions are secured by the following means of adjustment. The stop-cocks can be made stiff in the usual way, by tightening the screws which screw the "keys" in the heads; the tension of the spring, *U*, can be increased or diminished by means of a screw at the lower end of the tube containing it; and the elasticity of the stop-cock can be regulated by means of the screws, *M M*. Although from this description, the operations of adjustment may appear complicated, it is, in fact, practically very simple. After the first time of use, it is rare that any further adjustment is required than a turn of the screws, *M M*. The diameter of the apertures at the end is necessarily smaller than that of the cylinder; it is, therefore, impossible for the water in it to be entirely changed while descending through a distance equal to its own length. It raises a question, therefore, for experiment to decide what actually was the rate of change of water. To this end, a few experiments were made in fresh-water lakes. The bottom being filled with water containing some yellow prussiate of potash, was sunk in the lake, until the surface of the water was on a level with the stop-cock, when the stop-cocks were opened, and the line let go. On being brought up again, the contents were treated with the solution of sesquioxide of iron. It was found that, when the bottle had been sunk to a depth of a fathom and a half, the water had been entirely changed, the solution being wholly without action on it. We may be certain, then, that the water which we obtain by this means is an average of the water obtained through the bottle has passed.

The weight used as a sinker should be chosen so as to impart sufficient velocity not to lose time unnecessarily over the operation, and, at the same time, not to give an excessive velocity at the depth where the water is to be collected, because the rate of change of water depends on a friction of the water inside the bottle, and so on the velocity of descent. In practice, for depths of 100 fathoms, a weight of 112 lbs. was used, and for depths from 25 up to 100 fathoms, a weight of 56 lbs. was used. For less depths the weight of the bottle itself was sufficient. The velocity of descent at the depth where the water is collected should not exceed 12 feet per second. The mean velocity for the interval between 75 and 100 fathoms from the surface was, with 66 lbs.,

nine feet, and with 112 lbs., eleven and a-half feet per second.

When once let go, it is essential that the line should run out to the required depth without a check; it is then, however, immaterial, as far as the water bottle is concerned, what interruptions occur in heaving in. The fulfilment of the condition of running out without a check never presented any difficulty on board the *Challenger*, depending as it does on the care of those who take the line. When, however, by accident a check does occur, the line is stopped, and the water-bottle brought up again, reset, and sent down again. In order to utilise any such accidents, it is usual to take the water from the greatest depth first; then, if a check does occur, it may occur at one of the desired intermediate depths, and so no time would be lost. In designing the water-bottle, it had been my intention to use it not only for collecting water, but also as a flask, so that the atmospheric gases could be boiled out of it without transvasing the water. In practice, however, I have not been able to get air-tight stopcocks, besides which, it would make an inconveniently large apparatus in a very small laboratory. I have spoken of this water-bottle as being only used for intermediate waters, but there is no reason why it should not be used for bottom water; indeed, where the sounding lead does not weigh over 1 cwt., it is frequently used for this purpose. In the case of deep soundings, however, where a weight of three, and sometimes four hundred-weight is used, the "slip" water-bottle is always preferred.

#### DISCUSSION.

A Member asked how the depth of the mud at the bottom of the sea was determined; and how the instruments would be affected by it, because when the instrument touched the soft mud, it would not act as it would if the ground were hard.

The Chairman said that having been Commander of the *Challenger*, it was scarcely necessary to say how important he considered the subject on which Mr. Buchanan had been speaking. It was most important for telegraphic purposes to know not only the depth of the sea, but its properties. The *Challenger* expedition had been found fault with for not adopting at once the present system of sounding, dredging, and taking temperatures; but all those things were progressive, and, thanks to Sir William Thomson and the telegraphic companies who were also interested in those matters, and to Mr. Buchanan who was working at it independently for the love of the thing, satisfactory progress had been made. They were pretty well satisfied with the present apparatus for sounding, for which purpose they now all used wire, because they could get the sounding so quickly. In fact, when laying telegraphic cables, a second ship, with a wire-rope and lead 35 lbs. in weight, could follow and measure the depth every 20 or 30 miles as they went along, and keep up with the one paying out the cable at the rate of five or six knots an hour. In taking serial temperatures, great care was required, because the thermometers were so valuable—not exactly in themselves, although they were very delicate instruments—but because on the return of a ship after three years' work, the thermometers which had been used in those observations were worth any amount of money for reference in future, their errors having been determined. At present, therefore, they had not sufficient confidence in wire-rope for temperature soundings. As regards dredg-

ing, they now learned that telegraph ships had given up the wire-ropes for picking up old cables, on account of the weight; so that at present wire was only used for soundings. The United States Government, in their operations in the Gulf of Mexico year after year, had attained a very high state of perfection. The English dredges were just bags which scooped up a cargo of mud, and could not be scraped along the bottom. But the Americans had improved upon that, and had an iron frame, in the form of a parallelogram, which was far more successful. The great desideratum now was, not to sound quicker, but to attain more exactness. As to temperature, they had got to the decimal part of a degree, which was near enough, but they wanted more information as to the movement of the water at the bottom. All the measurements as yet taken in connection with ocean currents and tidal movements, were on the surface; but there was a great deal of movement at the bottom, and a knowledge of it was very requisite, especially for telegraphic purposes. The motion caused by a heavy sea was not supposed to extend more than 40 or 50 fathoms down, but telegraphic cables were out at depths of from 300 to 400 fathoms, so that there must be motion going on down there. The barrier across the entrance to the Mediterranean was about 200 fathoms, or 1,200 feet, and water below that level did not get into the Mediterranean. If you sank a thermometer, it showed the same temperature at 200 fathoms as at 2,000, so that the bottom water did not move at all. In the Atlantic or Pacific, if a thermometer denoted that the temperature of the sea got colder and colder as the depth increased, it showed that in such places there must be an enormous movement of cold water, probably from the Poles, that cushioned up against the barriers, and got stopped. The great desideratum now, therefore, was an apparatus to denote the movement of water at different depths. With regard to the temperature of the mud at the bottom, when Sir Wyville Thomson and other gentlemen were sifting out the mud for shells and minute organisms, no matter whether they were on the equator or elsewhere, their fingers were nearly frost-bitten, and it was a constant practice to cool the wine by putting the bottles in this mud. A thermometer with a wooden case, such as had been shown, if sunk to the depth of a mile, would have the whole of the air in the pores of the wood squeezed out; afterwards it would sink at once in water, if immersed. Between New Guinea and Australia, the trawl often came up literally full of wood and leaves from the bottom, which must have become water-logged by the same means. In fact, there was a coal formation going on at the mouth of some of these rivers, which were not carrying down soil enough to cover the leaves and wood, which, as they got thoroughly soaked, sank, and kept sinking as they became more dense from the pressure of water, until they reached the bottom. It had been supposed that the water got gradually colder and colder as the depth increased; but in the Antarctic region, he felt perfectly certain that they tapped a stratum of warm water under the cold, though they could not measure it. He wrote home from Australia for such a thermometer as Mr. Negretti had now arranged. In the Antarctic regions, whether from the greater density of the water or from some other reason, there was a cold stratum at the top, then a warm stratum, and then a cold stratum again underneath. Similar observations were required near the North Pole also, but after all, the great desideratum at present was a method of obtaining observations of submarine currents.

Mr. Buchanan, in reply to the question as to the effect of mud on the sounding instruments, said that water bottles were so delicately slung, that the least support would tumble off: they did sometimes come up full of mud instead of water, but very rarely. He never remembered a failure from the sounding weight not

dipping. The only difficulty with the weight was that now and then it would choke itself by slipping the wrong way, but that very seldom.

The Chairman then proposed a vote of thanks to Buchanan, which was carried unanimously.

## INDIAN SECTION.

Friday, March 4, 1881; Sir RICHARD BART, G.C.S.I., D.C.L., in the chair.

The Chairman said, in introducing Mr. B. to the meeting, that he thought he could prove to have a paper both agreeable and interesting. He had known Mr. Maclean in India, who had been considered—and justly considered—an authority of the press. He wished there had been a larger audience on the present occasion, but not large, it was select. And he must request the reader of the paper that, through the *Jour. Soc.*, he had an appreciative and influential audience of between 3,000 and 4,000 members.

The paper read was on—

## THE RESULTS OF BRITISH RULE IN INDIA.

By J. M. Maclean.

Perhaps no question has been more hotly discussed of late years than the value to the people of the country of the political connexion between England and India. In less exacting times the benefits derived by the ruling power from all events, from an extended empire, were considered to be too manifest to require discussion. And while, a century ago, the American Revolution which revolted from Great Britain, gave champions of the justice of their cause to the British Parliament, the science of political economy was then so undeveloped, that statesmen of all parties agreed in deploring, as a calamity, that separation which is applied to certain Englishmen in our own day as one of the greatest blessings that could have been applied upon this country. On the Continent of Europe the old-fashioned view of the advantage of the State of Imperial dominion still holds it among the most advanced thinkers. I need remind you, for instance, of the opinion of De Tocqueville, in 1857, that it was the glory of India which secured to England the consideration she enjoys throughout the world, and that the loss of her great dependence would be quickly followed by her decline to the position of a second-rate power. In England, the modern school of political essayists, who rely themselves on their superiority to vulgar notions, are fond of maintaining that the abandonment of India by the British would increase the power and resources of the country. What is morally wrong, they say, is never politically right; and they are exercised with such uneasy questionings of conscience as to the justifiableness of England's holding a foreign country in subject, that they eagerly ascribe to it all kinds of excuses. Their way of thinking in this respect is like that of a distinguished Navy officer who on his voyage to Europe asked the

ular and Oriental steamer in which he senger to spread out before him the map rld, and show him what territories be- England, and who, after having had our ad dependencies in Europe, Asia, Africa, and Australasia pointed out to him, held ds in amazement, and exclaimed, "Well, ished that Heaven does not inflict some nishment on such a nation of land

But they believe that our insatiable ew possessions has brought with it its shment, and that, while England has dia materially by dragging her to the bankruptcy, India has, in her turn, ed the English people, by infecting them se desire for power and glory, instead of ve of liberty. Probably many Anglo-icials, after reading in some impassioned the mischief of keeping India, a fervid n of their own pernicious influence in g English society, must have been able to hat Warren Hastings felt when, at the

Burke's speech for the prosecution, ial at Westminster-hall, he said he was i he must have been a great villain, ie never knew it before. The only con-hey can have is in the reflection that these e, for the most part, written by young men, mbition to win a name as philosophical ds them to seize upon a taking subject, ch they have no practical acquaintance, and gloomiest pictures of the disastrous effects h rule in India are painted by persons e never set foot in that country, and who le or no acquaintance with the real cha- the English civilians and soldiers by whom rned. What wonder is it if the extrava-nd unfairness of such attacks excite a nt and sometimes unreasoning opposition, irritated Anglo-Indian officials set their one man against outside criticism, and vie o another in emphatically asserting that e the best of all possible administrations? ehave, on the one side, high-flown rhetori-ism which overshoots its mark, and, on the e prejudiced determination to defend, at all e system of government in which the candid t cannot fail to detect numerous imperfec-My aim this evening—and I do not conceal elf the hazard I run through interfering tral in such a quarrel—is to steer a middle etween these two extreme parties, and, tempting to give you good reasons for ing the doctrine that English rule in India purely mischievous results, to offer some criticisms on administrative defects, the of which is denied or overlooked by ptimists.

ardly necessary to insist upon the obvious gains which accrue to England from cession of an Eastern Empire. A simple tion of them will suffice. In the first is no slight advantage to us that the ent of India disburses in this country 3 millions sterling a year, out of the collected from Indian taxpayers. The nation, it is true, does not take this money e people of India without giving them g in exchange for it. The amount of the arges represents the value of munitions

of war, commissariat stores, and railway ma-terials sent out to India, interest on English capital invested in that country, and payments for skilled English labour employed in the Indian civil and military services, or in the construction and super-intendence of public works. But, for a country which has a good deal of capital and skilled labour to spare, as England has, it is an unquestionable advantage to find such safe, constant, and profit-able means of investment; and we have only to contrast the security enjoyed by the holders of Indian bonds, and the public servants of the Indian Government, with the anxieties and losses endured by Englishmen who have trusted in the good faith of other Eastern States, to get a measure of the pecuniary worth of our imperial supremacy. But the home charges only show the direct transactions between the Governments of England and India. The indirect gains of private enterprise in India are also very considerable. British India ranks now with France, Germany, and the United States among our very best customers. The United Kingdom supplies her with three-fifths of her whole imports of merchandise; and, while there were not wanting a year ago prophets of evil, who exulted over the falling away in the Indian trade, consequent on the famine of 1878, as evidence of the accuracy of their gloomy forebodings, and who predicted that it could never revive, but must continue to decline, it is satis-factory to observe that there was an immediate rebound after the good harvest of 1879, the imports of merchandise, in the year ending March 31, 1880, having exceeded those of the preceding year by more than three millions sterling, while for eight months of the present financial year, April to November, 1880, not only was this re-action maintained, but the imports of merchandise in-creased in value to 32 millions, against 24 millions in the corresponding period of 1879, showing a further rise of 25 per cent. Nor do Englishmen make profits only on the import trade into India.\*

The greater portion of the export trade from India is also controlled by English houses, settled in the Presidency towns; and four-fifths of the shipping engaged in the foreign commerce of India belong to British owners. If you trace the history of a bale of Indian cotton, exposed for sale in the Liverpool market, you will probably find that in all its successive stages, after being grown and picked by the native cultivator, it has been made ready for and brought to the market by English capital and labour. An English agent has selected it in the producing district; it has been carried down to the sea-coast by a railway company working with English capital; an English mercantile firm in Bombay has pressed it, and sold the bill of exchange against it through an English broker to an English bank; and it has been transported from Bombay to Liverpool on board an English steamer. So, again, with regard to the piece goods trade from this country, it is entirely financed and managed by Englishmen till the bales pass into the hands of the native dealers in the bazaar of Bombay. You will readily calculate how many different profits this vast trade, which may be valued at a hundred millions sterling, yields to all these classes of English manufacturers, merchants, bankers, middlemen, shippers, engineers, and other mechanical experts. And when you add to such mercantile gains the private remittances sent home by English traders and professional men settled in India, and by the civil and military servants of the Crown, you can realise how immense, in the aggregate, must be the contributions which our great dependency annually makes to the wealth of England. There is not a town, it may be said without exaggeration that there is not even a hamlet, in this country in which the fructifying influence of the capital thus acquired is not felt, although it may not be *always* recognised; and I do not know any industry

in the United Kingdom, small would not suffer loss, if the connection were broken off. But, it may be a valuable trade with India would remain if the country became independent. I do remain. The preference for Indian taxation, which is common to all enlightened nations, and which by many Englishmen, is on in India by the authority of the Government; and, if this were once natives would speedily raise a large the State revenue by levying produce on piece goods and other Indian goods, and would injure our country by granting bounties to native manufactures, too, of English civilisation modifying native customs and manners at least, and creating a taste and refinements of European life effaced, and a limit thus set to extension of our trade in the East conclude, therefore, that the material England are bound up with the our Indian Empire. Whether or sion of empire is morally better citizens of a free State is a more putable question. It is many years republican virtue of Professor took alarm at the liking for arbit which he detected in the large and of retired Anglo-Indians. So far, own experience goes, I think I Anglo-Indians generally hold ve about matters of domestic policy are rather inclined to make lig troversies about franchises and which, if we are to believe excit cians, periodically bring this brink of a revolution. It is quite t hand, that Anglo-Indians are, pe Imperialists in the best sense of th term; and possibly in the preser public mind, it is not to be regretted infusion of Imperialism should England year by year, from h dependencies in all parts of the imperial instinct is always active vigorous nations; it is nowhere energetic than in the United States and an observant companion of C his recent voyage round the wor Indians what he took to be the hig remarking that, in their political seemed to him to resemble Americ Englishmen.

I pass now to the consideration of a difficult branch of my subject—th on the fortunes of the people of land's relations with that country that the alliance between the mutually advantageous, or are of it enjoyed by one, while th the loss, not only of its political even of the legitimate reward and the natural increase of th earth? It is not too much to s believed by many Englishmen—s of persistent misrepresentation—brought to the brink of ruin by t

mercilessly imposed upon her. The phrase, "the Bankruptcy of India," is often used as if it were an actual fact, instead of the vision of an wrought and distempered imagination. The peace established throughout India is de-to be as baleful as the *Pax Romana* was to some provinces of the Roman Empire; but the re-pressed by the Roman historian to his men, *Solitudinem faciunt, pacem appellant*, apply in this case. England's crime, on tary, appears to be that, under her rule, a population has multiplied too freely for ductiveness of the soil; that the yearly wealth to England has so impoverished nry, as to leave no margin of the means of ce stored up against the years of famine recur at regular intervals; and that, conse-ly, when a scarcity comes, the people, taxed at most limit of human endurance, perish illions, because they have neither food enough me to eat, nor the money wherewith to purchase abroad. English Imperialism is, in fact, are told, killing itself by the exhaustion of its im. Well, this gloomy picture must strike with assessment anyone who is familiar with the out-nd signs of the steadily increasing prosperity of ndia. Can it be possible that a revenue steady in irth and easy of collection, that populous and ealthy cities, a flourishing foreign trade, the rapid evelopment of many new industries, and a general ise in the standard of living among the labouring eases of the population, which are the accepted marks of well-being in all other States, only con-eal in India a deep-seated disease which is wasting away the body politic? Let us examine attentively the statistics of trade on which the believers in India's impending ruin chiefly rely. I have already shown you how profitable this trade is to England, but we are told that it must be in an equal degree profitable to India, since that country, according to the Custom-house returns, exports every year twenty millions' worth of produce, for which she gets nothing back. The fallacy of this argument lies in the assumption that the Custom-house returns afford a complete balance-sheet of the transactions between the two countries. To find out what India really gets in exchange for her exports of produce, you must add to her imports of merchandise and treasure so many millions for interest on English capital invested in India in a hundred different ways, and so many more for the wages of the skilled English labour employed in her service; and when these additions have been made to valuations of the Custom-house authorities, it is found to be no loser by her foreign commerce. his conclusion is further borne out by an ysis of the kind of imports she receives. She not, as a poor country necessarily would do, back the value of her exports of cotton, op, seeds, tea, coffee, and spices in food and ing for her people. She imports what foreign handies she requires, and is paid the balance old and silver. Mr. Goschen's Committee of e, on the depreciation of silver, calculated that, e 40 years between 1835-36 and 1874-75, India ed, in round numbers, silver to the amount of 200,000,000, and gold to the amount of 1,000,000. The whole of this gold, and ably the greater portion of the silver, were

manufactured into ornaments or hoarded. Since 1876, when the opinion generally prevailed that a steady decline had begun in the Eastern demand for bullion, the imports into India have continued on the same scale, and it is not a little remarkable that in the famine year, 1877-8, they amounted to the sum, unprecedented since the era of the American civil war, of more than £15,000,000. Now it is surely preposterous to assert that a country, which is thus shown to be at the present day, as it has been for many centuries, "the sink of the precious metals," can be falling more deeply every year into a state of hopeless poverty.

But, it may be said, granted the unreality of the supposed drain of wealth from India, and that the larger amount of capital now devoted to agriculture, and the increased facilities of communication, give her a surplus stock of produce by the sale of which to foreign nations she can steadily enrich herself, still the question remains, if the wealth thus acquired is fairly distributed among the people, and especially among the cultivators of the soil. There must be something rotten in the state of any country in which wealth accumulates in a few hands, while the mass of the population become poorer every day. Now, a very strong opinion has recently been expressed by Mr. James Caird, who, as a great authority on agriculture, was nominated by the late Government a member of the Indian Famine Commission, that, "so far, our success in India has resulted rather in the conquest of vast possessions, than in elevating the individual man." The cultivator is, as a rule, he thinks, the slave of the money-lender. It is not, however, denied that the stock of capital available for investment in agriculture has increased, or that there is a steady extension of cultivation. If, nevertheless, the condition of the actual cultivator in some parts of the country has deteriorated, the cause of this decay must be sought in the habits of the people. The tendency of modern trade is to sweep away the middleman, by bringing the ryot, or peasant proprietor, into direct communication with the European markets, and thus enabling him to make larger profits on the sale of his produce; but no change of this kind can permanently benefit small holders, who have no money of their own, who think it a mark of respectability to be deep in their bankers' books, and who, by an honourable custom, make themselves responsible for their fathers' debts. The ryots of the Deccan had a magnificent opportunity of making themselves and their families for ever independent of the village usurer during the five years of the American civil war, when the price of Indian cotton was more than quadrupled. But they fancied, as the Bombay Government did, that this exceptional period of prosperity could be maintained; and so, while they, on the one hand, exercised no thrift, the Government, on the other hand, raised their rents, until, in the long period of falling prices which succeeded the American war, their situation became intolerable. The remedy sought by the Government for this state of things is the limitation of usury; but there can be no more grievous economical mistake than, in the hope of averting political mischief, to root an impoverished peasantry in the soil, and drive capital away from cultivation. But Mr. Caird goes on to say that the condition of

"the landless labourer" is still more deplorable than that of the cultivator. "Though wages have risen at the centres of industry, this is not the case in the purely agricultural parts of the country. In such localities the labourer gets the same dole that he got in the last generation. The numbers of such people are increasing, and their condition is becoming every ten years more desperate. Thus, the greatest difficulty with which the Indian statesman is confronted is over population, with constant increase, and his first and main duty will be to carry out a policy under which the people may be enabled to provide themselves with food. An exhausted agriculture and an increasing population must come to a dead lock." Elsewhere he says, "Population is increasing, the price of food is rising, the production of it, as shown by exports, scarcely advances; whilst, as the number of the landless class who depend on wages is constantly growing, the supply of labour, in the absence of industries other than agriculture, must soon exceed the demand. Already their wages bear a less proportion to the price of food than in any country of which we have knowledge. The common price of grain in the Southern States of America, on which the free black labourer is fed, is the same as that of the Indian labourer, viz., 50 to 60 lbs. the rupee. But his wages are eight times that of the Indian, 2s. to 2s. 3d., against 3d. a day, whilst the climate is much the same in its demands for clothing and shelter." The reply of the Government of India to this formidable indictment is an admission that "the population of some parts of India is very dense, especially in the Ganges Valley, from Saharanpur, in the north-west, to Tipperah, in the south-east," and that it is "in some parts, already too thick for the country and its produce." At the same time the Government maintains what, in face of this admission, would seem to be the paradox, that wages have risen in India during the last 20 years. The wages of skilled labour of all kinds have risen considerably, but even the wages of rural labourers show a distinct improvement." Dr. W. W. Hunter, in his recent lectures, seems to take almost as unfavourable a view of the case as Mr. Caird does. Speaking of the increase in numbers of the inhabitants of British India, he says:—

"The average population is now 211 to the square mile. How thick this population is may be realised from the fact that fertile France has only 150 persons to the square mile; while even in crowded England, wherever the density approaches 200 to the square mile, it ceases to be a rural population, and has to live, to a greater or less extent, by manufactures, mining, or city industries. Throughout wide districts in India, each acre of land has to feed a human being for a year. In certain smaller areas of Bengal, two persons have to live on the produce of each cultivated acre, or 1,260 persons to the cultivated square mile. We speak of the poverty and the miserably small farms of the Irish peasant. Well, Ireland has, according to the last census, 169 persons to the square mile. But we can take 13 districts of Northern India, equal in size to Ireland, which have to support an average of 680 persons to the square mile, or over one person to each acre."

I venture to protest against the tone of exaggeration which pervades criticisms of this sort. The average population of Belgium to the square mile

is 451; of England and Wales, 389; of 377; of the Netherlands, 291; of the empire, 289; of Great Britain and Ireland of Wurtemberg, 249, and of Italy, 237. therefore, is very far from topping the Germany, with a population of 193 to the mile, treads very closely on her heels. superabundant population of India is mainly found in the broad valley of the Lower which possesses a soil of unrivalled fertility capable of maintaining probably twenty times the population that could live upon an equal territory in the German Empire. Dr. declares that, "after a minute comparison of the condition of the Bengali peasant in our country with the facts disclosed in the old records, he is compelled to the conclusion that the struggle for existence is harder than when the country first passed into the hands of the British. I hope he will publish the evidence which appears to him to justify this conclusion. The opinion of employers of labour in other parts of India is that the Bengali is, as a rule, dependent on the inducements to emigration held out to him because he is, on the whole, tolerably well supplied with his lot. His wants are few and easily supplied; and when Mr. Caird contrasts the condition of the free black labourer in America, he forgets that Indian coolies have been under native no less than under British rule accustomed to do a comparatively slight amount of daily labour for wages which they can live on, but which would hardly keep body and soul together in any other country in the world. Indignation which is sometimes felt by Englishmen when they hear that in India the labourer at the rate of 4d. to 6d. a day is quite miserable. By religion and custom, all classes of Hindus are, as a rule, wonderfully abstemious; and the painted and jewelled head of the Peishwa of the Mahratta nation, sitting on his throne with his spear stuck in the ground by his side and making his dinner off a handful of grain, represents no extraordinary incident in the usual way of life of all the Mahratta princes and peasants. Possibly, even the rural labourer, earning his 12s. to 8s. a week, is compelled to live on animal food and strong drink, and to buy plenty of warm clothing, and unable at all times to guard himself against cold and hunger, might envy the Indian coolie his 4d. a day, who can be content with his rice or grain, and with, perhaps, only a rag for his loins, is secured by his genial climate from knowing what is meant by the cold, which is the worst enemy of the poor in Northern India. One thing that usually escapes notice is that of the general employment of Indian women and children in out-door labour. This custom, and the nominal rate of wages of the men, at the same time, it may treble or quadruple the earnings of each family.

The whole controversy about over-population resolves itself into this question:—Are the wages relatively higher or lower in India than the prices of food-grains than they were twenty years ago? It is unnecessary to go back in our inquiry, because, if the present exhaustion is really going on in India, it will be more plainly visible in its later

ages. The elaborate report of the Famine Commission contains no exact information on the subject, while some of the Commissioners assert that the economical condition of the country is, on the whole, improving, others are dissatisfied with it. As the evidence the Commission has not been published, no means of estimating the comparative value of these conclusions. I have thought, therefore, it might be worth while to collect information on the subject from independent sources. I have received from Mr. Middleton, a partner in the firm of Messrs. Glover and Co., the principal railway contractors, and, I should say, the largest employers of labour in India, a paper embodying the results of his many experiences in the North-West and Central Provinces. He says:—

**North-West Provinces.**—I am of opinion that the value of labour in general has increased to the extent of an average of 33 per cent.; some have less, but that the largest increase has been in the price of the common coolie labour. The reasons for this are various:—1. Increase of work, and the country being opened out by the railways. 2. Increase of acreage under cultivation. 3. The opening of various industries, such as cotton and the tea industry, and similar highly cultivated industries opened out by Europeans. 4. The opening of food caused by the facilities of drawing out the surplus for exportation of all surplus skilled labour has undoubtedly not made the ordinary working or coolie labour less. All this I attribute to a larger number being employed year after year as artisans—to my knowledge ryots and their sons as masons, carpenters, &c. I think although population has slightly increased in the North-West, the average of grain food raised has increased. The country has passed through a period of under-average crops, but in the history of other countries such visitations have been common. They were far more severe in their ancient times, through the want of information of transit for food, but that the country now overburdened with population is what no one acquainted with these provinces would be far from such being the case (I speak from personal experience), it is now much more difficult to find a large number of labourers on earth-shaking in the labour-key in this country) than at much enhanced rates, although they are not better. The working man is more independent and dependent for their daily food on the south system, and I consider that the largely use of railways, as means of moving long shows an accumulation of wealth which did not previously. Now, such accumulation could result from a smaller increase in the price of wages, and the price of food is a sure sign of the too dense or meagre population of a

**Central Provinces.**—Here there has been a large increase in the population, but not nearly in proportion to the increase of cultivation, and to the increase of returns. Nowhere in India have the people bettered their condition in the last ten years more than in this. Grain is certainly somewhat dearer, through the given by the Great Indian Peninsula Railway for exportation, but wages are quite 50 per cent. higher, through the agricultural population having increased of food-grains. Vast tracts yet to be brought under the plough, and these could support several millions more than they do. The district officers are doing their utmost

to import labour from the (so called) teeming population of Bengal and the North-West Provinces, the fields sigh in vain for the rural population they hold out such rich attractions to. From the above considerations, I am of opinion that, apart from increased skilled cultivation, India can yet feed on its present production a population greater than now depends on it."

Mr. Glover himself writes:—

"In the North-West Provinces and Rajputana, where I have been engaged in making railways since 1872, labour has not only risen in value by about 50 per cent, but it has become scarce in proportion, this scarcity being, no doubt, caused by the increased demand for labour on the fresh land taken into cultivation, and by the gradual extension of railways. Wherever a railway is made, labour at once increases in price very much, and has never again receded to the price paid when a line was first started. In Bombay itself labour has certainly increased in price from 30 to 50 per cent. during the past ten years."

This statement with regard to Bombay is confirmed by my own experience of the rise in the wages of domestic servants, and labour of all kinds, in the Presidency town, at all events; and one cause assigned for the deterioration in the quality of the recruits for the Bombay army of late years is that the soldier's pay, once thought very liberal, is now less than the wages which can be earned by the same class of men in civil life. A gentleman, who has had great experience in letting contracts for large works in and near the city of Bombay, writes to me:—

"In 1868-69 the rates for coolies on the roads was from 3 to 4 annas a day, it is now 5 annas. Two to 3 annas was the charge for women coolies, now the charge is 4 annas. The rates for skilled labour in 1868, as compared with those now paid were, a good mason, 8 to 12 annas, now R. 1 to R. 1 4 annas a day; carpenters, 8 annas, now 12 annas to R. 1."

In the rural districts of the Bombay Presidency, of course, the change has not been so marked. My friend, Mr. John Gordon, the secretary of the Bombay Chamber of Commerce, whose masterly papers on financial and economical questions are familiar to all persons interested in Indian affairs, has taken much trouble to supply me with tables, showing the variations in the prices of food and of skilled and unskilled labour throughout the different districts of the Bombay Presidency during the last ten years. These tables are printed on three following pages. I may say generally that they show very remarkable changes in the prices of food, while the rates for skilled labour have improved considerably in most districts, and those for unskilled labour have either remained stationary, or slightly increased. The food grains of Western India, jowari and bajri, are kinds of millet which are never exported, and which, therefore, are quite unaffected by the development of the trade with foreign countries. Their price varies with the more or less propitious character of the rainy season. Thus, in December, 1877 (a year of famine), only nine seers of jowari could be bought for a rupee in one of the rural collectorates, while, in December, 1880, 29 seers could be bought for the same money. The lot of the labourer, whose wages remain stationary, is, therefore, good or bad according to the abundance or scarcity of the seasons; and the evidence

of these figures, so far as it goes, proves that, even in districts remote from the centres of industry, the "individual man," whose interests Mr. Caird wishes us to care for, has not been injured by British rule.

Another conclusion, which seems inevitable from this necessarily imperfect survey of the state of India, is the supreme importance of public works in that country. The construction of railways is everywhere accompanied by a rise in the prices of agricultural produce, and high prices are a sign of

prosperity when the wages of labour increase we find they do, in at least an equal ratio. It is not the want of food, but the difficulty of obtaining it within reach of the people in the districts affected with a dearth, that caused the grievous losses in recent famines; and the description given by the late Lord Lawrence twenty years ago of grain rotting on the ground in the Punjab, and the want of the means of transport to markets, is still applicable to many parts of India. For it is not much to boast of that in the course

years we have built a system of trunk lines running over nearly 9,000 miles, in a country as small as Europe, excluding Russia. The United Kingdom adds nearly as many thousand miles to their railway system every year, while we creep along in India, maintaining an enormous and costly system to superintend the construction of only three hundred miles a year. This unwise policy has been endorsed by the Public Works Committee of the House of Commons in 1879, which only limited the annual amount to be expended on railways and irrigation works in India to £1,000,000; and it has its supposed justification in the case of the Indian finances. We are often told that taxation in India has reached its limit, and that still the revenue is insufficient to cover the constantly-increasing expenditure. It is a sufficient answer to this statement to say, that the total debt of India on 31, 1879, only amounted to £138,000,000, which amount £33,000,000 represents capital expended in public works, so that the debt against the Government holds no property does not two years' revenue. Without wishing to anticipate the budget which will be brought next week at Calcutta, I may safely say that the results of the present financial statement astound critics who refuse to believe in the city of India's resources, and who imagine must have been completed by the unfortunate ruler made last year about the cost of the war. Nor can it be pretended that the debt is raised by an oppressive system of taxation.

The salt tax alone touches the poor; though it is, in some respects, objectionable as all taxes are—there is no other general consumption which is used in all quantities as salt, so that the duty paid by each consumer is infinitesimal.

As to the richer classes, there is no nation in which their position as regards the payment of taxes is more enviable than in India. For many years they even, by persistent petition, succeeded in getting themselves exempted from taxation in any form, while the taxes they pay are quite trifling. This being the case about Indian finance, I would put it to you as a largely increased annual expenditure on public works, and especially upon railways, called for in the interest of the country. The Government, which receives more than £10,000,000 a year from the land, to which it has the place of a landlord, is bound to lay a considerable portion of this revenue in works to increase the productiveness of the soil, to give cultivators improved means of access to markets; and such judicious expenditure is amply repaid by the consequent rise in the value of land and rent of land.

What way should these works be executed, by private enterprise, or by the direct agency of the Government? Lord Dalhousie reconciled the two by joint-stock companies to raise railway capital under a Government guarantee; and this system worked well, for the guaranteed lines are better built and economically managed, and they now pay the full 5 per cent. interest, not exercised by the State in return for the guarantee prevents the companies from using their privileged position by

charging excessive rates and fares. But some years ago, when railway traffic was not yet developed, and the State suffered a heavy annual loss from having to make good the deficiency of interest at the guaranteed lines, the Government of India resolved to have nothing more to say to private enterprise, but to make its own railways for the future. It hoped thus to effect a great saving of money; and, to make assurance doubly sure, it determined to change the Indian railway gauge, and construct a system of narrow gauge lines, which would at least be cheap, if they were not so good as the broad gauge lines. This experiment was begun in 1870, and we are now able to assert that it has completely failed. From Mr. Juland Danvers's last report, it appears that about 2,500 miles of State railways had been constructed up to the end of 1879, at a cost of £25,000,000, so that the average cost has been £10,000 a mile, a rate at which private companies could easily have built the lines on the broad gauge. The working of the State lines, again, compares unfavourably with that of the guaranteed lines, the expenses of management forming a much heavier percentage on the gross receipts, so that the net earnings are only at the rate of about £1 3s. per cent. per annum. Nor is the real cost of these lines fully shown in Mr. Danvers's report. The Indian Government, when it determined to construct its own railways, allowed the companies' experienced engineers to leave India by the score, while it founded an engineering college of its own at Cooper's-hill to supply recruits, who go out with all the practical part of their business to learn. The heavy cost of maintaining this college, and the pensions of the engineers trained in it, ought to be added to the charges for State railways. The chief cause, however, of the excessive expenditure on these lines has been the unfortunate decision of the Government to introduce the narrow gauge into India. Surveys were made, and hundreds of miles laid down on this gauge in Northern India, before the military authorities were able to convince the Secretary of State that break of gauge would be a fatal defect on lines intended for use in time of war; and then all this work was suddenly abandoned, and the gauge of the Punjab Northern and Indus Valley lines made uniform with that of the broad gauge system of the rest of India. The only important trunk line which the champions of the narrow gauge have succeeded in keeping in their hands is the newly-opened Western Rajputana Railway, which completes the direct connexion between the seaport of Bombay and the cities of Delhi and Agra; and, with regard to this line, the Governor of Bombay said the other day, on opening it, that it was so inadequate for the traffic, that before many years were over it would have to be taken up and reconstructed on the broad gauge. You can conceive what a blunder has been made with this line, if you will suppose for a moment, that London had no railway connection with Manchester except by a roundabout railway through York, and that, on a direct line being projected, the State insisted on having it built with a much narrower gauge than that used on all the lines in either the north or south of England. Evidently, such a break of gauge would defeat the very purpose the line was intended to fulfil, that of making communication

between London and Manchester quicker and more convenient, and this is exactly what has been accomplished by the Government of India with regard to the line from Bombay to Delhi.

I have insisted on this case at some length, because it illustrates what I take to be the cardinal defects of our administration in India, namely, the grasping love of power which too often distinguishes high officials, their insensibility to public opinion, and their dislike of private enterprise. The members of the Government of India are usually high-minded, able, and personally disinterested men; but, quite unused to freedom of debate, they cannot bear contradiction, and may even, as in the instance I have cited, be betrayed into spending millions to gratify a crotchet, rather than give way to outside criticism. Hence, it is sometimes said with truth, that India is the most theory-ridden country in the world. With the exception of one or two eminent officials, everybody, Europeans and natives, in India, condemned the adoption of the narrow gauge for the Western Rajputana line. The communities most deeply interested sent up to Simla protest after protest, only to have them treated with disdainful silence; the Government of Bombay itself remonstrated as warmly as it dared, till at last it received orders from the Viceroy in Council to say no more on the subject; and so, without excuse, without attempt at justification, this great wrong was done to the political and commercial interests of the country. Then, with respect to the construction of railways generally, any impartial observer can see that it would be better for India if the execution of new lines were entrusted to a number of companies, who would go on with the work rapidly and uninterruptedly, than that it should be left to a Government which cannot but act capriciously, and, therefore, wastefully, since works begun and half carried out are often stopped on account of the outbreak of a war or a famine, or merely out of deference to the prejudices of some new minister. The present prices of Indian railway securities in the English market show that the rate of interest to be guaranteed to the companies need not now exceed that at which the State borrows money itself. But the Government of India has always been jealous of private enterprise, and this jealousy shows no signs of abatement. The enterprise of unofficial Englishmen, hampered as it has been, has done great things for India. There is hardly an article of Indian agricultural produce exported, the trade in which has not been created or developed by English enterprise, and this animated agency has also initiated the cotton and jute mills, and other industries that are now providing diversity of occupation for the labouring classes. Yet what is the reward of these English adventurers, who ought, if properly treated, to become the mainstay of the administration? India is the only part of the British Empire in which the English merchant, planter, professional man, or tradesman is absolutely shut out from having any share in the government of the country. He pays his taxes, and the Government kindly allows him to join a volunteer rifle corps; nay, the compliment is sometimes paid him of asking his advice on legislative measures which affect his interests, and which are afterwards passed into law in utter disregard of any adverse opinion he may

have expressed; but the Indian will not suffer him to enjoy a particle of authority, and it compels him to abandon of permanently settling in the country. The partially self-governing municipalities have been formed in the great cities, which unofficial Englishmen have tried their taste for the management of public affairs, but the officials keep a firm grip on the reins. A prefect is set over the corporation, in leading-strings; and the mode of electing members is so contrived, that the Government always find the means of suppressing municipal independence. Mr. Fawcett lately invited India to English capitalists, as a fair investment. If he wishes capital to flow into India, let him and others interested in the matter—no matter to which political party they belong—remove, first of all, the political obstacles which are so keenly resented by all Anglo-Indians outside the official circle. The present mode of administering the country seems to be to reproduce the great German historian of Rome has said as the political condition of an empire in which there were no Romans but "civilian officers, and schoolmasters." I, for one, believe that the English Government should strike root in India until it has become or rather allowed to grow up, a strong class leavened throughout by the English. As a matter of policy, high posts in the administration should be reserved for others than Government servants. In each of the provinces, as well as in the Colonies, the Governor-General, the control of the administration corresponding to the Board of Trade, should be entrusted to men practically conversant with mercantile affairs; and such appointments as Commissionerships of Customs, of municipalities, and of Harbour Boards should be regarded as the legitimate reward of private spirit among non-officials. Nor can I see any reason why the Railway Department should be superintended by royal rather than by private engineers. It is a curious circumstance that an agent of an Indian railway, who, in 1862, would never have been thought eligible for appointment in the executive Government, was selected years ago to be the director-in-chief of the Egyptian railways. The Egyptian Government was clearly more liberal than that of the India. I would finally ask, with reference to the subject of my subject, if a solution of the difficulty connected with the maintenance of a European force in India might not be found in the employment of men for special service in that country on condition that at the end of a certain number of years they should receive grants of land with their families in India. A chain of colonies might thus be formed, which would strengthen our hold on the country.

The next best thing to the adoption of a generous public works policy that could be done for India, would be the abandonment of her exclusive and selfish policy of not allowing any attempts to restore the value of silver as a medium of exchange. Cruelly India suffers through the depreciation of silver will be apparent when you consider the public remittances alone to the Home

the loss to Indian taxpayers amounts to £3,000,000 a year, and that the effect of a value of the rupee to 1s. 10d. would be a sufficient to cover the occupation of Kanda. But the depreciation of the rupee is also felt by private remitters, by the holders of securities of all kinds, and by owners of property in India; and, while a low rate of exchange unquestionably exercises a stimulating effect on the Indian export trade, it has, on the other hand, the compensating disadvantage of lessening the purchasing power of India as a consumer of foreign goods. The monied interest of England is also very shortsighted in refusing to listen to the complaints of India on this score, and is contentedly declaring that a gold currency is good enough for England, and that other countries must look after themselves. An able writer has recently argued, with much force, that the steady decline in prices which is still going on in England, and which especially affects land, is the result of the growing scarcity of gold, and that that metal has become the only measure of national value, and the time may come when the value of all kinds of property will be affected, the purchasing power of England diminished, and deprive her of that control of the market of which she is now so proud. While she still can command as much as she wants, it might be prudent for her to ought to the interests not only of foreign countries, but of her own great eastern dependency, and send a representative to the Conference to meet at Paris next month to consider means of readjusting the value of silver and gold.

It allows me to speak of the reductions that are made in Indian expenditure, but I believe it is right in saying that the higher ranks of the Civil Service in India are too well paid, and taken into consideration how few of the ties of exile a residence in India now is. It is in the home charges, however, that there is scope for economy which will be found in garrison, and furlough, and allowances of late years is quite startling; in the military department, in particular, the effect of reforms in the organisation of the army is to be a steady increase in the amount of non-effective charges in England. Last year the amount expended in England for the salaries of officers of the Indian service, including colonels' allowances, was £1,205,874. The small-mall and St. James's-street swarm of Indian officers, while the supply of men for duty with native regiments in India is diminished as to reduce many of them to a mere efficiency. Then the cost of the India Office at Westminster has increased, is increasing, and is not to be diminished. It now amounts to £215,804, against £173,000 in 1865. The business of the Government is done in London, and the work of supervision in England, and the India Office ought to be by far the most important of our departments of State, but it costs as much as the War-office. Its disorganisation is, that it provides for a Council of Indian experts, at an annual cost of £100,000, without counting the salaries of its staff officers and clerks, to advise the Secre-

tary of State chiefly on matters of finance. The late Mr. J. S. Mill applauded the constitution of this Council as the most successful of modern applications of the science of representative government; but experience has shown that it is of very little use, except to provide additional pensions for eminent Anglo-Indians. The House of Commons has practically taken the control of the Indian finances into its own hands; and, after the confession made by the India-office, last year, that it had not the means of detecting or remedying the blunder made in India about the Afghan War estimates, one may well ask what the financial supervision of the Council of India is worth. Surely, it would be better for the country if the Secretary of State could no longer reward a partisan, or silence an adversary, by giving him a place in the Council of India, and if eminent Anglo-Indians, on retirement from service in the East, entered public life in this country, and gave the nation the benefit, in the House of Commons, of the matured advice and criticisms which they now whisper vainly in the obscure recesses of the India-office.

One administrative reform which would certainly have the effect of changing the character of our rule in India I have not yet referred to—I mean the proposal for the more extensive employment of natives in the higher ranks of the administration. The Government of India, in its comments on Mr. Caird's report, declares itself in favour of a change in this direction, and says:—

"We have before us, and have referred to the local governments for consideration, a scheme of recruitment whereby the total strength of Europeans in higher offices might ultimately be reduced to 571 for the whole Bengal Presidency."

I confess that I should look upon the accomplishment of this scheme with great uneasiness, and, indeed, with alarm. To maintain the existing bureaucratic system of government in India, merely substituting native for European agency, would, in my judgment, be a fatal mistake. There would be no economy in such a change, because, unless you paid the natives as liberally as the Europeans, they would be dissatisfied, and the administration would consequently become inefficient and corrupt. Again, European civilians in India have even now too large a body of native subordinates interposed between them and the population. This is one great cause of the want of knowledge of and sympathy with popular feeling, which is often made a matter of reproach against them. Reduce their numbers still further, in order to increase those of native officials, and the English portion of the administration will be left completely in the air. All the machinery of government will be managed by natives, and in troublous times the English raj might be overthrown by official conspirators before the mass of the people knew what was intended. Of course, this may be the consummation desired by those persons who contend that we ought always to be preparing to leave India and to give back the country to the natives. But, though I have known many Englishmen who would talk about educating the natives of India for independence, I have never met one who would fix any date at which this transfer should be accomplished, or who was not ready to vote for spending the last drop of English

blood and the last shilling of English money to prevent such a catastrophe from happening in his day. This talk about India's future independence is, therefore, only the counterfeit coin of a false sensibility. I confess that I do not believe India can ever attain independence. Her people dread leaving their own country and crossing the ocean, and her coasts and foreign trade have, therefore, always been, and must continue to be, at the mercy of whichever power has the command of the seas; and the national character is so unwelcome that, even if Hindus and Mussulmans forbore fighting with one another, they could not hope, without European protection, to resist the inroads of stronger races from the north. England may then, with a good conscience, continue to hold India, if she takes care to act fairly and justly towards the people of that country, and tries to level them up to the enjoyment of constitutional liberties by proceeding cautiously in the path of decentralisation, and steadily enlarging the limits of municipal, and ultimately provincial, self-government, while at the same time maintaining the distinctively English character of the administration, and cherishing to the utmost, instead of endeavouring to efface, the English element of the population. By such a policy we should, I am persuaded, do more good to a country, in whose future I take the deepest interest, than by making it over to the tyranny of a native bureaucracy; and, by persevering with it, we might hand down to our successors our imperial inheritance undiminished in strength and lustre, hoping that from them in turn it would descend to following generations with "better title, better opinion, better confirmation." It should, indeed, be the most ardent aspiration of every true Englishman that, for the sake of both countries, the connection between England and India may never be dissolved; that it may never be said of our native land, in the mournful language of Wordsworth's epitaph on Venice,—

"Once did she hold the gorgeous East in fee,  
And was the safeguard of the West;"

but that, for ages to come, England may still retain these proud titles to the admiration and the gratitude of the civilised world.

#### DISCUSSION.

Mr. Petersen said he had listened with very great interest to the paper, and generally speaking, he agreed with the remarks made in it, but time would not allow him to comment as he would desire upon some of the suggestions it contained. Neither directly nor indirectly would he run a-muck against the authorities who held the government of India. As India had to be governed by us, we must make the best of it, and maintain our rule in the country at all hazards, and at any cost. If England were to desert India to-morrow, and the country were left to itself, more terrible scenes of bloodshed than the world had ever seen would ensue, and India must become the prey of some northern nation, whether Russia or China. Our Cassandras at home were altogether too fond of running down the connection of England with India, but he could testify to the improvement in the country during his own connection with it, as a sailor and as a barrister, since 1829, and if the prophets of evil were better acquainted with the actual facts, they would spare many of their utter-

ances. Famine must ever be a visitant or parched under the tropical sun, and dependent on necessary moisture on irrigation works, respect it could not be gained that God done its best during many past decades. As employer of labour in India, he might say years he had hundreds of coolies at work a day, and the rate of increase in wages the fact that, when he left India, they cost at ten pice a day; and as to the value of districts, seventy-two seers, or 144 lbs., were a rupee, while at Patna, a rupee would purchase five seers. That was not the case now. He said that the condition of India had deteriorated since English rule. There were many points in that rule upon which he could have dilated, but he never been a particular supporter of the Government. He would say that, as far as in them lay might have done more, they had ruled in any other country had ever governed a district. The question of the grain supply, people who were going to the dogs had to recon- sidered the astounding facts that the value of labour had very greatly risen, and more grain had been produced the people existed in the country. Trade and necessities of humanity, and although from position of traders we had been compelled conquerors in India, we must support our extending her commerce. Damage had been done by our supremacy to the condition of the people, certainly not to the working class, general amelioration throughout the country what we had done, let our own Cassandras say what they might. Our efforts were quite as much for our own benefit as for Anglo-Saxon energy was necessary for Aryan spirit was simply again flowing arouse the torpor of the Asiatic. Asiatics themselves have started railways, and the them had, in fact, been opposed by the British of the consequences following in their the destruction of caste. The paper was alive in its scope to be fully discussed. Its publication in the *Journal* there would be of commenting upon the topics in. A population of some 34,000,000 in the Hastings had, at the period when Sir G. was in office, increased, it was estimated. Such an advance in the numbers of the best test of increased food supplies, the people were better fed. From his the Bengal Coal Company, which was employer of labour, he could speak personal condition of the working population also, who had any interest in the tea- how much the price of labour had could, personally, give no information the North-Western Provinces, but who about the improved condition of the labour certainly applied to Eastern Bengal. was going on in India, she was the most specimen of the process conceivable, increasing population, higher rates larger exports. Excessive taxation was proach levelled at the Government; he believe that, at the present moment, the large a revenue over the whole country from it by the Emperors Akbar and Aurang-

Sir James Wylie, Bart., said his country India commenced sixty-one years ago, there was a good deal said about the ar Decan, and about our territories being scribed. He had since then made rep had been struck with the extraordinary condition of the native population. He

the same parts of India in 1842 and 1846, and on returning there in 1870, was astonished at the great increase in the prosperity of the country. From his experience while in the House of Commons, where he served as one of the Indian Inquiry Commissioners, until last year, he was acquainted with the remarkable increase in the number of wages of the working population, and he had obtained from the Commissariat Department a list of prices, during 30 years, of the articles required for the sustenance of the army. Those returns showed that the prices had actually been from 30 to 60 per cent. higher in the latter years of that period, and they were to be found in the appendix to the report of the Select Committee, before which he had laid them. His experience, therefore, thoroughly bore out that which was the paper.

Mr. Joseph Payser, R.S.M.I., F.R.S., regretted that the paper generally was one upon which he was ill-qualified to speak, but he would venture to say a few words on the improved sanitary condition of the country, which was a matter more within his knowledge. Certainly in that respect there had been great material improvement during the last half century, as was shown by the fact that the death-rate had been reduced from 50 or 60 per 1,000 fifty years ago to 15 or 16 per 1,000, by the operations of the Government. Though he was not prepared at the moment to give figures, he believed also that the average of life among the native population had greatly increased. He could quite confirm what had been said about the improvement throughout the country in other respects. On the question of colonization, referred to in the paper, though he expressed opinion with great misgiving, and could not very easily give exact data for his belief, his own conviction was that the Anglo-Saxon race would never colonize the East of India. He had, it was true, seen instances of second and even third generations of Anglo-Indians, and matured in the country, but they always bore on them significant indications of decay. His own view was that European colonists could never have any permanent existence in the plains and valleys of India, and how far they might be acclimated in the high and hilly regions he would not say. That was one of the questions for consideration in the future of the country.

Mr. John Kellison, C.S.I., agreed with almost every word in the paper, but must make a qualification on behalf of himself and other retired Indian officers, as he had referred to the reference made to unfortunate persons who had nothing to do but to walk up and down the Mall. He hoped, by long service in India, he had deserved some provision on retirement, and having returned at last to England, they were able and ready to render further service to their country.

Mr. Samuel Aitken, on the subject of public works in India, also agreed with most that had been said in the paper. As Mr. Maclean had pointed out, the break of the wheel not only been a great misfortune but was quite bad for, as indeed had been the 5 ft. 6 in. gauge railway fixed. The Indian Government began the railways in a bad way. Instead of adopting gauge found efficient in other countries, they had a Commission of experts to consider the matter, and everybody knew that whenever that was the case the experts were sure to go wrong. Experts' views were very valuable in guiding practical men, among themselves they would be led by the most headstrong, who was generally the most wrong-headed of all. That was the case in India when the railways were being planned; and three engineers having been appointed as a committee, decided that the 5 ft. 6 in. gauge gave the best results, and that was selected in consequence to the 4 ft. 8½ in. gauge, but the 5 ft. 6 in. has been found, after a long trial in other parts

of the world also, to be too wide. Then General Strachey adopted the metre gauge. A railway was wanted up the Indus Valley, and the Governor-General in Council determined that that gauge should be adopted. At Simla, in 1869, he (Mr. Aitken) was asked his opinion upon the matter by a member of Council, and he replied that he thought it was a mistake, but that it was more a military matter than an engineering one. He was informed that Lord Napier was very much against it, but, in spite of this, the result was that the Public Works Department carried their point, and the railway was commenced on that narrow gauge, and had to be altered. And so it was with all the public works. The harbour at Kurrachee was originally designed by an engineer of great experience in harbour construction, but a military engineer, who had ideas of his own, thought proper to stop the works, and so they remained for six years, when the original plans were allowed to be carried out, and the works were found to be eminently successful. Harbour works at Madras, too, which had been attempted to be stopped, but they had lately turned out to be a great success. The fault was not so much that these matters were left in the hands of one set of men or another, military engineers or civil engineers, for men were very much alike, and there were good and bad in all professions; but, in public works, publicity was wanted, and before any works were undertaken, or, at all events, before any money was spent on them, a public inquiry should be opened. At present, these matters were all managed by resolutions in Council, founded on papers, which, if read by the members of Council, he felt pretty sure, would often not be understood by them. Open inquiry, such as was made by the House of Commons upon public works, was what was needed, and that would ensure common sense being brought to bear upon the construction of such works in India. It would be very desirable also to give companies more scope for private enterprise, unfettered by the Government; it was of no use trying to put them in leading strings, as had occurred in the case of the Madras Irrigation Canal Company. The Government should content itself with offering guarantees of so much money per mile on railways, and leave the companies to sink or swim by their own exertions, getting no money if they failed, but if they succeeded, then, so much the better for them. He certainly agreed, therefore, with most of the opinions expressed in the paper, radical as they were on several points.

Mr. Jaland Deavers demurred to some of the remarks as to official obstruction contained in the paper, coming, as he did, from the particular hive where the bees were described as receiving too large a share of the honey for unnecessary work. Some of the points touched upon should be adverted to, lest the meeting might be under misapprehension with regard to the desire of the Government upon the question of executing public works through private enterprise in India. Mr. Maclean spoke favourably of the guarantee system, and it had undoubtedly been the means of producing beneficial results to the country. It had simply been adopted for want of a better, and without any idea originally of the control on the part of the Government, which became necessary as soon as they became interested in the returns of the railways. Twenty-five years ago the first attempt was made to assist a joint-stock company in this country to raise money for works in India, but it failed. Efforts were then made in other directions to induce English capitalists to provide money for the construction of Indian railways, but it was found that nothing short of an absolute guarantee would suffice. Within a comparatively short period, under the guarantee system, upwards of £100,000,000 had been expended upon railway works; but at any time the Government would have rejoiced to find that public works required in India would be undertaken.

entirely by private enterprise. Capital is much wanted in India, and for the erection of cotton and jute mills, and for the opening of coal mines and other industries it has been forthcoming. Many such undertakings were being conducted without any help from the Government, and they might hope that better times were coming in regard to works of public utility, so that before long the artificial and objectionable security of the Government guarantee would not be necessary, in order to attract capital to India. Obstacles would never be placed in the way by Government. Surprises could hardly be felt at some of Mr. Maclean's remarks on the management of the Public Works Department in India, but some excuses could be offered in its behalf in the circumstances in which it was placed. It had been in an experimental stage, and was in a transition state. Such conditions always involved expense, trouble, and difficulty, but it was to be hoped that was now past, and that the success of the existing railways would lead to the introduction of purely private enterprise, which would neither be opposed nor hampered, but heartily welcomed by the Indian Government.

Mr. A. Rogers thought the remarks in the paper on decentralisation suggested the germs of most extensive reforms in the Indian administration, and he sincerely hoped that the attention of statesmen, both in India and England, would be directed to the subject. Until a few years ago, the financial administration was entirely carried on in Calcutta, but the central administration had been considerably relaxed, and more power entrusted to the local Governments in financial matters. People who knew India would admit that that had produced a beneficial effect; and it would hardly be denied that local affairs could be managed better in the provinces than by the central Government at Calcutta, at a great distance. He hoped to see the system still more extended in administrative as well as financial matters, as he believed the people had great powers for self-government. Education was spreading among them, and they were becoming more and more fitted to manage their local affairs.

Mr. J. T. Wood desired to say a few words on the subject of the metre-gauge railway and guarantee systems. There appeared to be now traffic more than enough on the Indian lines to fully develop the capacities of the metre-gauge, and the time had perhaps come for an alteration of that gauge in some instances. That work would not be very difficult, it had been done on several occasions in America by proper organisation of labour and application of materials, and it had been shown that a great number of miles of railway could be altered in a few hours in that respect. He would venture to say that 100 miles of railway could be altered without stopping the traffic for more than a few days, and in saying so, he would be far within the mark. As to the guarantee system, there was no material difference between that and the actual construction of the railways by Government, because they were making railways with the money borrowed at the ordinary market-rates in England, and they would not be paying less *exorbitant* prices by guarantee, because the rate of interest in England had fallen within the last few years from five to four per cent., at which the Indian Government could borrow any money they required. People might say what they liked, but the difficulty in making railways by private enterprise was that the public had more confidence in the superintendence and check of the Government over such works, than they would have in the promoters of them. Directors of companies might be men of the highest honour and probity, but still people in this country had lost so much money by railway enterprises, that they considered the Government guarantee a check upon even their own selected officers. It had been said that people might make railways anywhere in India if they chose to find the capital for the purpose, but the Acts regulating the construction of

railways had to be complied with, and the material Government check on private enterprise could not, under those circumstances, see the investing public in England were concerned much difference between the giving of guarantee construction of railways by the Government money borrowed in this country. Upon exchanges, he was afraid that any more currency would not have the effect material difference in the value of the rupee from commerce one article of barter would what was wanted was a universal currency. Britain and her colonies and dependents should be no impossibility, however un- greater desideratum of a universal currency whole civilised world might be, for Austral joined in the scheme, and a measure of value as possible, not confined to a single coin should be adopted. Whether the adoption of currency would alter the value of silver, different matter, and he had never been stand why these two questions were separately. Another subject which had alluded to, was the recent working of India; and one point of great public interest in connection with it, was the relative right in the Government, and in private individual gold fields. If their possession by the exception, he failed to see how the would have any great effect on the future change, and if the property in them belonged to the Government, that would be an advance towards obtaining a universal Great Britain and her colonies.

The Chairman, in proposing a vote of Mr. Maclean, thought the meeting would (the Chairman's) introductory remark, to expect to hear from that gentleman as would be both interesting and eloquent as the representative, to some extent, classes, he could scarcely endorse the entirety, though he thoroughly concurred in general tenor. It would have been time permitted, that the official side of points should have been fully stated. He very satisfactory to have heard from non-men so much in confirmation of the impression the country; and that, after all, afforded of the official ability with which the ad had been conducted. Though not an engineer, not refrain from adding his own testimony devotion and professional ability who engaged on public works in India, in service of the Crown or as, in technical engineers, had displayed; and whatever be found with the constitution of the Department, or with the manner in which had been carried out, the public works constituted a grand record written by England the land, and a worthy monument of British scientific skill. Cooper's-hill College, it was now being placed on a broader and basis, and it would probably receive would serve their country at home, as destined for service in India. That must supply a great desideratum for India, and education. He asked to be excused at from going further into many of the intentions which had been touched upon in a new light upon matters of the greatest interest and Anglo-Indians.

Mr. Maclean, in returning thanks, for the impossibility of doing justice to so within the limits of a short paper, and than refer the meeting for further

and Temple's own valuable work, published from India. With regard to the observation of public works, and the encouragement of species in carrying them out, he believed that we more cheaply in that way than when executed by the State. Government-constructed railways were costly, both in execution and management of the guaranteed lines, but at the same time, it was very useful in preventing monopolies as to the public. He had feared some of the paper might be distasteful to Sir Richard, but he had full confidence that their Chairman would receive criticism upon questions of such great importance, and he would conclude his remarks by proposing that the meeting should join in thanking him kindly presided.

His thanks were cordially passed, and the meeting terminated.

#### SEVENTH ORDINARY MEETING.

Friday, March 9th, 1881; Lord ALFRED DUNELIN in the chair.

Following candidates were proposed for members of the Society:—

Francis James, The Rowans, Lee-road, Lee,

Edward Clive, K.C.S.I., C.I.E., Ascot.

W. H., Wentworth-house, Manresa-road, W.

William, Meadow-head-house, Livesey,

St. 7, Bayewater-hill, W.

Liam Bernard, 54, Regent's-park-road,

Edward George, 26, Palace-gardens-terrace,

W.

Colonel Major G. S. W., 8, Belsize-avenue,

N.W.

Edel George, 63, Tulse-hill, S.W.

rd, 143, Lewisham High-road, New-cross,

Ericks Anthony, Kinross-house, Cromwell-

, and 85, Gracechurch-street, E.C.

Following candidates were balloted for, and members of the Society:—

Thomas, Kimberley-house, 2, Evering-road, Winton, N.

rd, London, Upper Canada.

, J.P., Ellingham-hall, Bungay.

Robert George, A.I.C.E., Manchester, and Lincolnshire Railway Company, Man-

chester, Cornwall-terrace, Penzance.

The reading was—

#### OF CHIMBORAZO AND COTOPAXI.

By Edward Whymper.

I am invited by the Society of Arts to lecture to you upon a journey which I desire to take to the great Andes of the Equator. I may perhaps think it strange that anyone interested with mountain travel or mountaineering should be brought before you; but if you have a moment, you will at once perceive that mountaineering is a high art, and is worthy of being encouraged by the public. Up to this time, most of the loftiest por-

tions of the earth are totally unexplored, and this arises principally from the fact that the mountaineer, in addition to experiencing most of the troubles which are met with by other travellers, has to deal with some which are peculiar to his work. I do not now refer to the distressing hæmorrhages, alarming vomitings, and painful excoriations which are said to afflict him. Hæmorrhages and excoriations are rather alarming words, so long as they remain untranslated into ordinary language; but they do not seem to be so very formidable if they are called bleeding at the nose, and loss of skin through sunburn; and it may also somewhat tend to allay alarm, if I say that I have never known cases of bleeding at the nose occur in mountain travel, except to those who are subject to the complaint; while, with regard to vomiting, it has only been known to occur to persons who had taken something to disagree with them. But there is another trouble, which cannot be dismissed so lightly. All travellers, without exception, who have ever attained great altitudes, have spoken of having been affected by another complaint, and this complaint is known to affect even natives of those regions, and persons who have lived in them, as well as casual travellers. This is usually called mountain sickness. There have been numerous conjectures put forward as to its cause; very often it has been supposed to be the work of mysterious spirits, sometimes it has been attributed to weakness, and other causes, but there can be very little doubt that it arises simply from the diminution of atmospheric pressure as one goes upward. At 20,000 feet the pressure is less than half the amount that it is at the level of the sea, that is to say, whereas at the level of the sea the atmospheric pressure is generally capable of sustaining a column of mercury of 30 inches, at 20,000 feet it will not sustain a column of 15 inches. Now, those of you who have witnessed experiments with the air-pump, must know that remarkable effects can be produced by reducing the pressure of air. I well remember the first occasion on which, when at school, I saw an old and shrivelled apple placed beneath the air receiver, and I watched with glees its wrinkles disappear gradually under a diminished pressure, and the apple fill out again, until at length it became as plump as it was in the days of its youth. The effect I then witnessed struck me as so remarkable, that I at once determined to see if I could not recommend its further application, and on my return, home, I suggested that the appearance of my grandfather would be greatly improved if he could be put under the air-pump; but as this application of science to my progenitor caused an application of something else to me, I have ever since regarded myself, in a small way, as a martyr to science. From seeing air-pump experiments, and other purely philosophic considerations, it is obvious that the human system must be liable to derangement, if subjected to sudden diminution of the atmospheric pressure to which it has been accustomed. These depressions have often been so severe as to render mountain travellers incapable, and their lives well nigh unendurable, so it is scarcely to be wondered at that they have endeavoured to escape from the infliction, by descending into lower regions. I do not know of a single instance of a traveller, who

having been afflicted in this way, has deliberately, so to speak, sat it out, and had a pitched battle with the enemy. Nor am I aware that anyone has ever suggested the bare possibility of coming out victorious from such an encounter. Yet upon doing so depended the chance of pushing explorations into the highest regions of the earth, and I long felt a keen desire to know whether my own organisation at least could not accommodate itself to the altered conditions. From considerations which would occupy too long to enter into now, I gradually acquired the conviction that patience and perseverance were the principal requisites for success, and the journey of which I am now going to speak was undertaken with the view of bringing this matter, amongst other things, to a definite issue. In the course of it we camped out at very great heights, twenty-one nights were spent above 14,000 ft. above the level of the sea; eight more above 15,000 ft.; thirteen more above 16,000 ft.; six more above 17,000 ft.; and one more at 19,000 ft. I shall not now anticipate what you will presently hear, but I have made these preliminary observations to render less frequent interruptions of the narrative, and for the purpose of explaining allusions in it which might otherwise perhaps have been only half understood.

Fifteen years ago, when my apprenticeship to the art of mountaineering was finished, and I cast my eye over the map of the world in search of new districts, it was not long before it was directed to the great Andes round about the Equator, they being, perhaps, the mountains of the most exalted reputation, and of great elevation, which still were little known. The highest of the group, Chimborazo, long accounted to be the loftiest mountain in the world, had received the attention of travellers of great celebrity, and in recent years its ascent had been essayed by French, Germans, Americans, and Ecuadorians. All had failed, and each succeeding failure increased the desire I felt to annex it to my own country. To-night I shall speak to you of Chimborazo and Cotopaxi alone, and I select these two mountains on account of the contrast which they afford. The one is capped by eternal snow, and the other burns with perpetual fire. Chimborazo is an extinct volcano, while Cotopaxi is an active one, and is, I believe, the loftiest volcano in working order.

I left Southampton for this journey on November 3rd, 1879, and arrived at Guayaquil on the 9th of the following month. At the time of my arrival, this town was affected considerably by the war between Peru and Chili, and its inhabitants evinced the most impartial desire for the success of both sides. It has been described by previous travellers as a place where there is always something doing, either there is a revolution going on, or an earthquake, or a fire, and this description is fairly accurate; and when I tell you that assassinations were occurring in the streets every day, you will perceive that it is a place well suited to a person of adventurous temperament. Besides this, it may be mentioned that the rivers round about swarm with alligators, and the surrounding land with snakes, many of the most deadly kind. I was not in the town during the wet season, but I am informed that at that time the river overflows the exterior land, and that the non-amphibious vermin

in general climb posts and trees, and exhibit most extraordinary spectacle. You see a hanging by the tail from rails, sitting on top of posts, struggling and writhing in all of inconceivable ways to escape from the all while associated with them are scorpions and kinds of strange creatures for which science scarcely a name.

From Guayaquil, we went by a river to Bodegas, and at that place our may be said to commence. My party consisted of two Italian mountaineers (cousins), Jean and Louis Carrel; a Mr. Perrin, whom I picked up at Guayaquil, to interpret the number of mules and muleteers. The route followed was the grand route to Quito, and all the trade from the coast to the interior over it. Its difficulties have been much exaggerated. It is a track, or series of tracks—generally narrow, often very muddy; and there is a constant passage of mules, well laden with the most valuable goods. Sometimes "Perrier Jouet" champagne found assorted with iron bedsteads; then one sheet of corrugated iron laid flat across the backs of donkeys, or a grand piano carried on the backs of six or eight Indians. In the reverse direction you have droves of beasts, often 20 to 30 in a group, coming to the coast, bringing huge barrels of quinine bark, accompanied by gangs of shaggy Indians, who, for the most part, are very civil. Labourers generally have a good day or a night for the traveller; but, in respect of language they employ to their beasts, I can say that, in comparison, the observations of an angry London cabman are decent, and those of drunken bargemen are moral.

Three days' travel from Bodegas brought me to the town of Guaranda, and here I found a portion of my heavy baggage, which had been sent some months in advance. This town is situated in a straight line from Chimborazo, which was the central point of the journey. Many of you probably under the impression that Chimborazo is often seen from the Pacific. There is an elegant passage in Prescott's "Conquest of Peru," describing the magnificent prospect which it affords to the mariner. The fact, however, is that very seldom seen from the ocean. Captains going up and down the coast say that they do not see it more than three or four times in 13 or 14 years. And, when I tell you that it is distant 91 miles on a direct line from Guayaquil, and from that point is elevated less than 2° above the horizon, you may form your own idea as to its magnificence from the Pacific Ocean, which is 66 miles still farther away. Up to this time we had not seen Chimborazo at all. We started from Guaranda on December 1st, still continuing the Quito road, and passed the southern slopes of the mountain to see if we could commence to make out a route which should promise a chance of success. We came right up the mountain before we saw any part of it, from that day the summit was always enveloped in clouds. It was obvious we could only go as far as we could see; so we returned to Guaranda, and until the summit was clear. Whilst returning, I was overcome with dizziness, feverishness, and a severe headache, and had to be supported by two people for the greater part of the way. Imagine that I was attacked by fever, I took 30 grains of

plate of quinine in the course of the night, and was covered up with mountains of blankets, but next morning there was nothing the matter. As the symptoms were those which occurred at a later period, when we were undoubtedly leaving the low atmospheric pressure, I ultimately concluded that it was through this that my indisposition was caused. At this point, allow me to say a few words further in regard to the troubles which occur to persons who go to great altitudes. Although the heights of the Andes, which we were about to visit, had been well determined, there was reason to believe that several of them approached, if they did not exceed, 20,000 feet. At the time of our expedition there were only three tolerably authenticated instances of persons having reached that height on land, and I could learn nothing which was of the least service regarding the experience of those who were engaged in those expeditions. But from others who had reached altitudes of from 17,000 to 20,000 feet, I heard a confirmation of my supposition that, at such great elevations, I ought not to expect a continuance of the immunity from mountain sickness which I had hitherto enjoyed. I put up my mind, therefore, before we left, that, now or later, we should suffer like the rest of the world; but, being of opinion, as I have already said, that patience would overcome mountain sickness, it was my intention, on all our expeditions, first to establish camps as high as we could force the natives and mules; and, as it would be impossible to retain the natives at those positions, it became necessary to provide ourselves with food sufficient for weeks, or even months, so that, in the event of our success in our enterprise, from badness of weather, mountain sickness, and other causes, we should have the mortification of being obliged to abandon our positions simply from want of sustenance. And as it could not be expected that we should be able to obtain on the spot the provisions which would keep for such a length of time, I concluded that the only safe course was to provide ourselves, from the first, entirely independent of the resources of the country, in the matter of food which should be consumed at the greatest rate. About two tons weight of the most portable and most condensed provisions went out for our use, and, irrespective of the things which were already already tinued, more than 2,000 tins were packed down. If time would permit, it would be interesting to enter into details respecting our outfit, but I must do no more than say that our provisions were arranged in boxes weighing 75 lbs. each. Two of them made a mule-load, and each of them held three tin cases, packed down, each of those three tin cases containing food for four days for one man. They included everything necessary except water and the preparation of these provisions and the packing of the outfit occupied almost as much time as the performance of the journey, and it appears not desirable to say this much on the subject, to any persons who should be tempted to follow in our track should be inclined to doubt our veracity, though finding it impossible to progress with the same rapidity. A great saving of time was effected by arranging the food in this manner, and the small journey was made, which was calculated

to occupy two men for four days, I had only to say take ten cases, instead of continually calculating, and then being afraid that candles, salt, or matches might be forgotten.

After two days more, we saw the upper part of Chimborazo for the first time; it appeared to be fine, and so I sent off two guides to select a camping place on the ridge we had examined on the 19th, whilst I completed the preparations for the journey. They returned on the 23rd, very much fatigued, having found a place which was suitable at a height, so it appeared afterwards, of 16,500 feet above the sea. Then Christmas came in the way, and our start was delayed until the 26th, when we at length got off—a caravan of nineteen persons and fourteen mules. Shortly before our departure from the town, I had the honour to receive a visit from the political authorities, and I did not at first perceive what was the object of the interview; but just before they left, the principal official thus addressed me:—“Señor, we understand perfectly that, in an affair like yours, it is necessary to dissemble a little, and you, doubtless, do perfectly right to say that you intend to ascend Chimborazo, a thing which everybody knows is impossible. We know perfectly well what is your object; you wish to discover treasure which is buried in Chimborazo, and, no doubt, there is much treasure buried there, and we hope you will discover it; but we also hope that when you have discovered it you will not forget us.” “Gentlemen,” I said, “I should be delighted to remember you, but in respect of the other matter, the treasure, I venture to suggest that you should pay half the expense of the expedition, and take half the treasure we discover.” But this idea was rather too speculative for them, and the interview produced no result.

On our way up, we went over the Quito track, and then, leaving the road on our right, we bore away directly towards the mountain. Night set in just as we were fairly arrived at its foot, and we encamped at a height of 14,400 feet, having risen 5,500 feet in coming from Guaranda. During the night two Indians, who had been acting as porters, deserted, and five mules also ran away. Our carrying power being thus reduced, it was necessary to make two journeys from the first camping place on the ridge, to a place very near the summit, S.W. by S., where the Carrels had selected a place for the second camp. Jean Antoine went away with the first detachment, and Louis and myself returned to fetch up the others. The rest of us then went up and arrived at about a quarter to five in the afternoon, having risen about 2,100 feet. We were now more than 16,500 feet high, and established ourselves there with provisions enough for three weeks, and with fuel enough for several days. All water had to be obtained by melting snow, of which there was enough round about us, and to keep up our stock of fuel and communications with the world below, I retained a muleteer and one beast to go backwards and forwards between our camp and the nearest hovel.

All the rest of our troop now left us, and did so very gladly; for although we had succeeded in establishing our camp on the selected spot, it had only been done by the greatest exertions on the part of my people and their beasts. The mules were forced up the very last yard that they could

go, and staggering under their burdens, which were scarcely more than half the weight they were accustomed to carry, stopped repeatedly, and by their tremblings and falling on their knees, and general behaviour, showed that they had been driven to the very verge of exhaustion. When we arrived at the second camp, we ourselves were in good condition, which was to be expected, as we had ridden up the entire distance from Guaranda; but within an hour I found myself lying on my back, along with both the Carrels, placed *hors de combat*, and incapable of making the least exertion. We knew that our enemy was upon us at last, and that we were experiencing our first attack of mountain sickness. We were feverish, had intense headaches, and were unable to satisfy our desire for air, except by breathing with open mouths. This naturally parched the throat, and produced a craving for drink, which we were unable to satisfy, partly from the difficulty of obtaining it, and partly from the difficulty of swallowing it, for when we got enough, we were unable to drink, we could only sip; and not to save our lives could we have taken a quarter of a pint at a draught. Before one-tenth of it was down, we were obliged to stop for breath, and gasp again, until our throats were as dry as ever. Besides having our normal rate of breathing largely accelerated, we found it impossible to get along without every now and then giving a spasmodic gulp, just like fishes when taken out of the water. Of course there was no desire to eat; but we wished to smoke; and even our pipes almost refused to burn, for they, like ourselves, wanted more oxygen. This condition of affairs lasted all night and all the next day, and I then managed to pluck up spirit enough to get out the chlorate of potash, which, by the advice of Dr. Marcet, I had brought in case of need. Chlorate of potash was, I believe, first used in mountain travel by Dr. Henderson, in the Cara range, and it was subsequently ordered by Sir Douglas Forsyth in his mission to Yarkand in 1873-4. The surgeon to the expedition states that he distributed little bottles of it amongst the members of the embassy, and says that, from his own experience, he can testify to its value in mitigating the distressing symptoms produced by a continued deprivation of the natural quantity of oxygen in the atmosphere. Before my departure, Dr. Marcet urged me to experiment, with a view to confirming this experience; ten grains to a wine glass of water was the dose recommended, to be repeated every two or three hours if necessary. I say distinctly that I thought it was of use, though it must be admitted it was not easy to determine, as one might have recovered just as well without taking any at all. Anyhow, after taking it, the intensity of the symptoms diminished; there were fewer gaspings, and in time a feeling of relief. I am so far in favour of its use, that I should always carry it on future expeditions. Louis Carrel also submitted himself to the experiment, and seemed to derive benefit, but Jean Antoine, the elder of the two, sturdily refused to take any doctor's stuff, which he regards as an insult to intelligence. For all human ills, for every complaint, from dysentery to want of air, there was, in his opinion, but one remedy, and that was wine; most efficacious always if taken hot, more especially if a little spice and sugar were

added to it. His opinions on things were often very original, and I leant whilst in his company; amongst other things that for the cure of headache, no more can be mentioned than keeping the head and the feet cold. I am bound to practise what he preached, and I can see no more curious sight than that of this man, lying nearly obscured under a pile with his head bound up in a wondrousment of handkerchiefs, vainly attempting a short pipe, whilst gasping like an eel, his naked feet sticking out beneath the blankets, when the temperature was much below the freezing point.

It seems curious to relate that Mr. Perrin should not appear to suffer at all, and except in the fire going—no easy task, for the fire to suffer from want of oxygen just like the fire, and it required such incessant blowing to consider for the future a pair of bellows a dispensable part of a mountaineer's equipment. Mr. Perrin behaved on Chimborazo in a different manner—he melted the snow, brought and attended to our wants in general, therefore, somewhat against the grain, he was in very poor health in consequence of having led rather a dissipated life, and he was so far debilitated that he could not walk a quarter of a mile on a flat without desiring to sit down, or 100 yards on a steep side without being obliged to rest. He was aware of his previous history, he certainly not have accompanied us. You will enquire—How can you account for this, with his shattered constitution, who, as a mountaineer, being unaffected, when who were all more or less accustomed to ascents, were, for a time, completely overcome. The explanation appears to be this. Mr. Perrin had been for a long time resident in the heights of from 9,000 to 10,000 feet, and several times passed backwards and forwards over a height of over 14,000 feet. The elevation at which he had resided for the last 10 years was, in all probability, higher than the mean elevation at which we were now living, and it would probably have been that he had been subjected to examination, that of respiration, and even his organs, were better adapted to a pressure of 18½ inches, which was the height of the mercurial column at the second camp.

On December 29th, the Carrels were in a better state, and were eager to be off except to send them away to continue the ascent on which our camp was placed. I intended not to go to any great height, and to another and higher camping place. The ridge was trap—I have a sample—it was shattered by frost, and even in a state of ruin. Just above our tent was a stony waste, and patches of sand. Higher up it became a little. Then its angle diminished, and were large snow drifts on each side; the crest of the ridge was composed of sand and frozen ice. At 18,500 feet the

an end. It was crossed by some precipitous rocks, and after passing these, you entered on the snow region which crowns the mountain on all sides. On the east of this ridge we had rather considerable glacier, which was fed, if not entirely formed, by the ice which fell from above, and at its sides there were sheer cliffs, over which the glacier which caps the mountain was projected. The mass of glacier which fell from these cliffs tumbled over the precipices and the slopes at their base 3,000 feet before they were arrested by the glacier beneath, and in the course of falling brought away numerous fragments. The glacier was laden with small ice blocks and the rocky fragments which it brought down, and we accordingly called it the glacier of debris. These cliffs, and those which face them, are the most elevated and the greatest in the Cordillera, and they were quite sheer and inaccessible. They were composed of a number of marked strata, disposed with great regularity, and it was easy to identify the beds from which fragments had fallen on the glacier by the same stone. All were trap; some were vitreous; some stony, and they presented the widest variety of colours, from a delicate rose to a coarse red, and from pale grey to the black of the beds of basalt. The whole of the rocks, and I collected 30 varieties, are distinctly volcanic, and the fragments which still seem to linger on this matter are now finally disposed of. The very highest I obtained, from about 15,500 feet, is an ash cinder.

The Carrels returned soon after dusk, both extremely exhausted; they could scarcely keep on their feet, and threw themselves down and went to sleep without eating or drinking. Their condition, and the rest I heard next day, rendered it certain that our camp, as a starting place, was not placed high enough. It appeared that the Carrels, neglecting the instructions, had been towards the summit, and at a height of only about 19,500 feet. They found the route unencumbered, carrying no instruments, and only enough food for their own use, and had intended to look after, and yet came back quite exhausted. It was obvious, therefore, we should have to get still higher up before we could make exploration of the real summit. So soon as we were well enough, I sent Louis down to the tent to fetch up the tent, which had been left there, and as soon as it arrived, we were in a position to go forward again. On the following morning, I went myself up the ridge to look for a higher camping place, and found one on the eastern side on some broken rocks, at a height of 17,400 feet. By this time, I was in a rather better condition than the Carrels; my feverishness had disappeared, and my blood had resumed its normal temperature. The gasping I had nearly ceased, and the headache had gone. I will perhaps wonder how I knew I was in a high; for in regard to this matter one is often taken, and fever is supposed when it does not exist. By the advice of the distinguished physician whose name has been already mentioned, Dr. Marcet, I had provided myself with a registering thermometer, for the purpose of taking the actual temperature at great elevations. This was done, and, in respect of this matter, nothing need be said than that at our greatest heights the temperature of the blood was just as it is at

the level of the sea—higher during periods of warmth, and lower when unusually cold. But still, at its normal height, when the thermometer is at 60° or thereabouts, it did not appear to be affected by a low atmospheric pressure at all. In recommending me to take this little instrument, of which I have one in my hand, Dr. Marcet rendered me a great service, and amongst all the devices and instruments which have been pressed upon the attention of travellers in general, of late years, I know nothing equal to it in importance. By constant observation, I was able to detect the earliest advances of fever, and by taking proper steps in time, was able to get through the entire journey without having an attack of fever worth mentioning. Its expense is trifling, and it can easily be carried in the waistcoat pocket. When we were first laid on our backs by mountain sickness, it showed that my blood temperature amounted to 100·4°, but by the end of the year it had fallen to its usual height, viz., 98°. Still, although the more disagreeable symptoms had gone, we found ourselves remaining comparatively lifeless and feeble, with a strong disposition to sit down when we ought to have been moving. There was plenty just about this time to keep us moving. First the muleteer, who was retained to keep up communication, came up and reported that some boxes left in dépôt at the first camp had been broken open and robbed. This involved going down to make an inspection, and dispatching Perrin to Guaranda. Then we found a quantity of tinned-meat had gone bad, and we had a world of trouble over it. I had invested in a quantity of ox-cheek, and one tin had been placed in each of our cases. Upon opening the first case, I noticed that the end of the ox-cheek tin had bulged, and, knowing what that meant, I had it thrown away at once. One after another we found the same thing, and at once, on opening another, a most vile stench rushed out, and I found the ox-cheek had burst its bonds, and not only became putrid itself, but had corroded and ruined almost the whole of the food in the case. It then became necessary to examine serialim each case, to know exactly how we were off for food, and the end of the matter was, we found ourselves obliged to hurl over the cliffs, provisions that had cost us, in round numbers, £100.

It would be merely wasting your time to recount the troubles we had in the wind, hail, snow, and thunderstorms—which we had night and day—from which we suffered each and all. The snow fell occasionally as much as six inches at a time; it was always fine and granular, and not in flakes. But we had far more hail than snow, and it fell continuously. Thunderstorms visited us with unvarying regularity every day. These occurrences delayed our progress, and it took three days to move the requisite quantity of material up to the third camp. At length, on the 2nd January, last year, having passed the night at our highest station, leaving communication open in our rear, I conceived the time had arrived when we might prudently make for the summit, and on the following morning, at half-past five, the Carrels and I started, and mounted about 1,000 feet without any great difficulty. We had arrived at the rocks I have spoken of as crossing the ridge of the mountain. We were half way up this when a furious and intensely cold wind arose, and we found our-

selves compelled to abandon all the things we were carrying, and to fly for refuge to the camp, holding ourselves in readiness to start the next morning. This happened to be very fine and cloudless, and profiting by the steps we had made the previous day, we mounted by a fair road, crossing these rocks and getting to a height of about 18,400 feet at eight o'clock. We then bore away to the left, that is to say, towards the west, over a snow-covered glacier, and ascended spirally, so as to break the ascent. There were few crevasses; the snow was in good order, although steps had to be cut in it. I noticed that our steps got shorter and shorter, until at last the toe of one foot touched the heel of the previous one. At 10 a.m., at a height of 19,500 feet, we passed the highest rock, which, I have already said, was nothing but a volcanic cinder. For some distance further we continued our progress at a reasonable rate, having fine weather and a good deal of sunshine. At about 11 a.m., we fancied we saw through the heavy clouds which covered the whole country to the west, and shortly afterwards, being then nearly 20,000 feet high, we arrived at another plateau near the top of the mountain. The summits now seemed within our grasp; we could see both, one on our right, and another a little further away on our left, with a hollow plateau about one-third of a mile across between them. We remarked that in about another hour we could get to the top of either, and not knowing which of the two was the higher, we made for the nearer, but at this point the condition of affairs completely changed, the sky became clouded all over, wind arose, and we entered a large tract of dusty, soft snow, which could not be traversed in the ordinary way. The leading man was up to his neck, almost out of sight, and had to be pulled out by those behind. Imagining we had got into a labyrinth of crevasses, we turned about right and left to try and extricate ourselves; and after discovering it was everywhere alike, we found the only possible way to proceed was to flog every yard of it down, and then crawl over it on all fours, and even then, one or another was frequently submerged, and almost disappeared. Needless to say, the time went rapidly. When we had been at this sort of work three hours, without having accomplished half the remaining distance. I halted the men, pointed out the gravity of the situation, and asked them whether they preferred to turn or go on. After consulting together, Jean Antoine said, "When you tell us to turn we will go back; until then we will go on." I said, "Go on," although by no means feeling sure it would not have been best to say "Go back." In another hour and a half, we got to the foot of the southern summit, and as the angle steepened, the snow became firmer again. We arrived at the top of it about a quarter to four in the afternoon, and then had the mortification of finding it was the lower of the two. There was no help for it, we had to descend to the plateau, resume flogging the road, and floundering on, to make for the highest point. There again, when we got up to the dome, the snow was reasonably firm, and we arrived upon it at last, standing upright like men, instead of grovelling, as we had been during the last five hours, like beasts of the field. The wind was blowing at the rate of about 50 miles an hour from the north-east. We were getting wretched and hungry, without having

the means to satisfy ourselves. V trouble, a mercurial barometer was man grasped the tripod, another to give it shelter by a poncho wind, and I, myself, lay on my the snow watching the descent of It fell until it was 14.1, at a of 14° Fabr., which, when compare observation made on the same day at gives for the height of Chimborazo By the time the barometer was in its it was 20 minutes past 5 o'clock, and scarcely an hour and a quarter of dayling. We fled across the plateau at possible rate. There is, as you are aware, difference between descending and ascending snow, and as we had a huge trough already made, we moved down it parative facility. Still, it took near to extricate ourselves from that p then ran, for our lives, for our arrival camp that night depended on our be cross those rocks before darkness fell. We just succeeded in arriving at the although it became pitch dark before them; then we saw our camp fire, and disconsolate shouts of Perrin, who was as we came hurrying down, and we arrived soon after 9 p.m., having been out nearly on foot the whole time.

The hurried way in which we left made me desirous of ascending again, but that Louis Carrel was *hors de combat*, his foot frost-bitten. As soon as it could he was sent down to the nearest place he could receive attention, and I myself up two days longer at camp. On the 12th of January I rejoined and we then moved by easy stages to Machachi. We waited there for nearly a week before he could take the field again. This suffered very severely, but it is due to you it was through his own fault. On leaving the ascent, I remarked he was not well, but he said he was accustomed to it. Jean Antoine used gaiters of the usual kind, a pair which, from having the l continued all round, are well nigh imwater. In wading through the snow summit it was wet as well as soft, Carrel got his feet badly wetted, and wards they froze, whereas Jean Antoine returned to the camp quite untouched.

My residence on Chimborazo thus extended 17 days; one night was passed at 13,400 feet, ten at a height of 16,500 17,300 feet. During this time, besides going to the summit, I also went three times 18,300. When we quitted the mountain of mountain sickness had disappeared touch us again until we arrived at the Cotopaxi.

This is a convenient point, before going to Cotopaxi, to say a few words respecting the country and the people of the country, the manners and customs. The road to Quito already said, goes over the southern side of Chimborazo, and then goes down to Arenal, and so to Quito.

so, called Chuguipoquio, is for the most part a rough mountain track, but here again it is to a made road, which continues without variation to Quito. This is the only made road in the whole interior, and it is a busy one, a great many of life passing along it. In December, I reckon we met or passed not less than 1000 carts, and 500 persons every day. A newly-arrived European is somewhat astonished, that in such large traffic, the track should be left in such a villainous condition, but after having been on other so-called roads in the interior, his astonishment disappears, and he begins to regard the track as something very superior indeed. I am inclined to say I did not on any part of it find more than two feet deep, whereas on other roads we had mud three and four feet deep. Even this is considered a very good amount, and an old resident in Ecuador rebuked me for calling a road bad in which the beasts had sunk half way up their flanks. Telling him what he called a bad road, he said: "It is bad in which the beasts tumble down holes and vanish quite out of sight."

On the Quito road you meet with a great variety of character. A large portion of the population, probably one half, is composed of pure Indians who were found by the first Spanish conquerors. The remainder of the population consists of a mixed race. It is universally admitted that there are very many Indians of perfectly pure blood, whose families have never been in any alliance with whites, but it does not seem possible to find a single Spanish or European family which has not contracted with the Indians. We had many dealings with the Indians, and found them on the whole to be honest, truthful, and well-disposed.

They are certainly, for the most part, hardy, robust, and tolerably intelligent. They are very numerous. We saw extremely little drunkenness amongst them, except in the Province of Esmeraldas north of Quito, where they are very numerous and prosperous. The small number of drunken persons seen throughout Ecuador is very small, and I was inclined to regard the population as a very sober race, until I learned that it was the habit of the country when any one wished to go to bed and get quietly drunk in bed. This is a very interesting custom, and it might be supposed to introduce it amongst ourselves, but drunkenness is abolished altogether. The habit of the persons mentioned on the road, especially those concerned in the traffic between Quito and other towns in the interior, travelling for the sake of seeing the country is very unknown; but occasionally you meet with one a little out of the common, who is inclined to pay a visit to some neighbouring town. If such a person is generally worthy of notice. If he is got up correctly, he will be wearing a so-called Panama hat, a straw hat rolled up, and costs any sum from about £10. To take care of this precious hat, he puts on a white outer casing, and as it gets spoilt by the rain, he puts an oil-silk on the top of that, so that he has three hats over the other. To protect his eyes, he ought to be wearing a pair of blue goggles, which are sold in Birmingham at half-a-crown a

dozen, and, in Quito, at half-a-crown a-piece. Outside he will probably have on a poncho of superior quality such as this, and underneath it a coarser one. What he may wear in the guise of trousers I cannot say, because they are covered with buskins made of the skin of some wild animal. His feet are very nearly invisible, and if you see them, you will most likely notice his toes peeping through his shoes, but, for the deficiency thereabouts, he makes up in the heel by his spurs. Here is a specimen of these articles, but this is considered a moderate thing in spurs; I can assure you many are worn more than double the size. Altogether he is what we should call a regular guy. But we have not yet done with him. If he is properly turned out, he carries at his button-hole a drinking cup, which may be carved and silver mounted; at his side a tremendous chopping knife, which is used either for cutting away branches or as a tooth-pick. If he is a person of great distinction, he will be strong in his whip, which will have a wrought-iron handle, as it is found that one of that description does not break so readily on the heads of mules as wooden ones. He will also carry a guitar at his saddle. Such a person, according to the phrase of the country, is a great cavalier, and if only decently mounted, he may aspire to marry any woman in the land. It is needless to say that, in roads in the state I have described, there are many accidents to baggage animals; beasts get stuck, their loads are thrown off, and sometimes abandoned, but what causes, I believe, far more loss, is the pilfering which takes place, and which it is almost impossible to prevent. I have been offered bottles of brandy by persons on the road, who, I am quite certain, could not have come honestly by them, and I have seen wine cases taken off a mule, taken indoors, opened, a bottle or so taken out, the case fastened up again, and loaded. To illustrate this I may tell you a case which was related to me on a visit to a fraternity of Jesuits. One of them said to me, "Señor, you know that the wine of this country is both dear and bad, and we thought that if we imported it ourselves, direct from France, we might get a pure wine at a moderate price; and so we ordered, as an experiment, a cask from a French house, but it cost us very dear. When it arrived, we were glad to find that it was full, and that it did not leak; but I am sorry—oh, I am sorry to tell you, that when we opened it, we found that it was full of very dirty water." These accidents, and the weight of the heavy duties which are imposed are, no doubt, the main cause of the high price of foreign goods at Quito, and in the interior generally. An ordinary quart bottle of "Bass" costs 4s., and a pound of English salt, 3s. 4d., while a common iron bedstead, that would be dear in London at 50s., I have seen marked at £9. Accidents notwithstanding, these prices appear to leave a good margin for profit, and an enterprising man could probably make 100 per cent. on his transactions. You must remember, however, to take into account an unknown quantity of earthquakes and revolutions. You may be a rich man one day, and a bankrupt the next. Trade in these regions may be said to possess all the excitement of gambling without its immorality; but it does not appear to be very fascinating to the English, for,

at the time of my visit, I found only two of my countrymen in Quito. In touching on morals, I tread on delicate ground, because what the Ecuadorians consider moral, we should term immoral. I shall, however, relate one instance, which conveys a vivid idea of the manners and customs of the country. Some years ago, the late Archbishop of Quito, who was a much respected man, moved to indignation by the immorality of some of his flock, tendered a reproof; but some sons of Belial, in revenge, stole into the vestry on the occasion of an important church festival, and put strychnine into the sacramental wine. The Archbishop partook of it, and fell dead before his people. This incident created so great a sensation, that the authorities forgot to punish the assassins, who are still at large, and—perhaps, to prevent a repetition of such things in future—they suppressed the Archbishopric, and seized a great part of the revenue. You have here developed in this single instance a gross, immoral, and atrocious crime which is left unpunished, and a flagrant disregard of vested rights. As this is the description of the people themselves throughout Ecuador, you will see good reason for the non-interference of strangers in their politics. I studiously avoided meddling with their concerns; still it was not possible to be any length of time in the country without hearing a good deal about its domestic affairs, and in some respects these are both interesting and edifying. The Parliament, or House of Assembly, it is said, comes together only on rare occasions, and when it meets it manages to do without all-night sittings, and its members obey the ruling of their President, and vote exactly as they are wanted. It might be worth while for her Majesty's Government for the time being to send a special commissioner to Ecuador, to learn how this desirable state of affairs can be arrived at. Then with respect to finances, they manage extremely well. There is no augmentation of the public debt, for the simple reason that no foreign country will lend them money, and the inhabitants are far too wise to lend it to each other. This universal distrust arises from the undeviating habit of repudiating contracts. No bargain ever seems terminated, and in respect of this matter, one of the most respectable and honourable of foreigners in Quito told me that he never considered a transaction completed until he had given his customer a whipping. The marks of the whip, it seems, answer the place of a receipt stamp. The Ecuadorians are, as I have said, a very interesting people, and there is much that is curious and amusing in their manners and customs, but it is most pleasant to study these at a distance.

In passing from Chimborazo to Cotopaxi, we go from an extinct volcano to an active one, and to one of the most terrible volcanoes in the world. It is situated, roughly, north-east from Chimborazo, at a distance of 65 miles. From Quito, it bears south-east about 33 miles. Three years ago, during the last great eruption, ashes from it fell in Quito to such an extent, that it was pitch dark at mid-day, and persons in the streets in front of their houses could not tell where they were. On this occasion, too, there was a great manifestation of flames, which rose to an enormous height; the

larva rapidly liquified, and poured down in torrents, which caused rivers six miles distant rise 60 feet above their ordinary height, and, for instance, I was informed, it carried away a bridge 100 feet above the stream in the village of Antigua, where a cotton factory was established 25 miles from the mountain; the whole was razed, and the heavy machinery was carried 30 miles down the river. All round the mountain the natives have stories of the tremendous ravages which occasionally occur. General opinion seems to be, that the peace and greatest activity are always preceded by a period of repose. In fact, it is said of the mountain that it is of children, when it is quiet it is sure to be in mischief. During my enforced stay, I fell ill last March, I was in the immediate neighbourhood of this mountain, and abundant opportunities of studying its behaviour. It was unusually tranquil, and though fretting and fuming, and giving occasional growls, conducted itself on the whole in a well-behaved manner. I several times remarked that during the night much less smoke or vapour came away from the crater than during the day, and this led me to conclude that if we could pass a cable on the summit, we should be able to see to the bottom of the crater, a sight no one had hitherto enjoyed. So far as one could judge by examination with the telescope, it did not appear that it should be able to find a reasonably protected place on the all but naked final cone; so, in addition to the troubles which were likely to occur from living at a great altitude, we had the chance of being blown up by the mountain, or being blown down by the wind.

All our arrangements were carefully made, and we started for Pichincha, passing at first through a small hamlet, then turning west, and then up a ridge of the mountain, and descending towards the west, and encamped at a height of about 15,000 ft. As the transport of our camp equipage, all through, was beyond the power of the Carrels, I called for volunteers amongst the natives, and those who came we proceeded to dress up in accordance with our views of propriety. The native dress is well suited to mountaineering as it can well be; commencing with a straw hat, which always flies away; then a long poncho, a variety of blouse with a slit in the middle, through which the head is passed, and this is sure to fly up in your face at the critical moment; then rough shoes, which, although not unsuited to ordinary use, are totally inadequate to snow or rock-work. The rest of their attire of the most flimsy description. I am now, of course, of the inhabitants of the interior living at a height of 8,000 or 10,000 feet, at which there is an almost invariable temperature of 60 degrees. In the lower country much less is worn, and they seem to have attained, in some cases, the perfection of simplicity. I hold in my hand the entire dress of a native of St. Miguel Colorado. This is a fit dress either for a game party or an evening assembly, and as it appears to be some connection between the necessities of attire and perfect bliss, you may judge yourself when there, if not in Paradise, at least not far from the Garden of Eden.

On the 16th we sent up the first instalment

res to the final cone. The weather was very with a varying temperature, and I did not till the 18th. The view from our camp led over a large expanse of country, by cracks and fissures, in every direction covered with cinders and blocks of lava. It was curious that although the cone, for at six or seven miles in all directions, was dotted with lumps of scoriae, which, from the rim which it was dotted about, appeared to lead from the crater, I could not learn that any considerable volume had ever descended on the part of the natives. Some had the idea that they had ever been thrown in respect of fire, water, and ashes, everything to say. They generally agreed that flames were frequently seen to rise from the rim of the crater, and that even when it is not flowing, and ashes are not being

In the morning of the 18th, we started before six, and at half-past six arrived at the edge of the crater. We had so far improved in condition that when between 18,000 and 19,000 feet, we took 360 steps without stopping, and only became tired because our men were tired. The ascent was not so difficult; almost the whole way over snow up to one, and then over ash mixed with ice. The cone is the steepest part of the ascent, and its side presented an almost continuous slope of 35 degrees.

As we ascended, and from a few feet of the edge we had to peer into the unknown. A vast quantity of smoke and vapour was boiling up, and only saw at intervals a portion of the crater, the bottom being invisible. We then made a place for the tent, with the aid of the natives. When this was done, we went back to the first camp, and the Carrels remained alone. The camp was necessarily on the outside of the final cone, which, at this time, was entirely composed of ash. This was not to the touch, and so loose as to render it a much trouble to fix the tent ropes, and a wind springing up, we carried out additional ropes, and attached them to the ropes we could find, and bury in the ashes. We fixed up a rope, as a sort of hand-rail, and immediately to the edge of the crater, and it was distant about 250 ft. We had completed the operation, when a violent storm, which threatened to carry our whole tent away. The poles of the tent quivered, and it was a question whether it could weather the squall. But the storm passed as suddenly as it arose, and for the rest of the day we were not much troubled by the elements. This was going on, we had another alarm. A great smell of india-rubber began to arise; and putting my hand to the side of the tent, I found it was on the point of melting; and placing a maximum thermometer on the floor it rose to 110°. As my feet felt at all warm, I tried in another place found on the other side of the tent it was in the middle 72°, whilst outside it was only cold, and in the night a minimum of 40° was shown in the temperature.

At about half-an-hour the crater

regularly blew off steam; no stones were observed. The steam appeared to be very pure; it rose in a jet of great violence from the bottom of the crater, and boiled over the edge, continually enveloping us. The noise made on these occasions resembled that which we hear when a large steamer is blowing off steam. We sustained scarcely any inconvenience from it, and this was the more remarkable since we had been well nigh stifled with sulphurous vapour about 1,500 feet from the edge of the crater when coming up. When night had fairly set in, we went up to view the interior, and saw the whole of its vast proportion for the first time. By measurements made on the following morning I find that the rim has a diameter from north to south of 200 feet, and from east to west about of 1,500. The rim is irregular, some points being considerably higher than others. The rock is trap; in the interior the walls descend to the bottom in a series of steps, and a precipitous slope of about a thousand feet. At the bottom there was a nearly circular spot of glowing fire, 24 feet in diameter. In looking at this, it was impossible to say whether liquid lava filled the pipe up to its orifice or not. Flames were flickering and travelling about in all directions, so that what was underneath them appeared more like incandescent than molten matter. The heat at the bottom of the crater was evidently intense, and far up its sides, in every direction, glowing fissures, from which flickering flames were also coming, showed that lava was red-hot below the surface, while columns of steam or smoke rising from hidden orifices, heightened the effect. It is impossible to conceive a more dramatic spectacle than this vast theatre represented, illuminated below by the subterranean fires, and above by a brilliant moon, whilst every now and then these outbursts of steam occurred, rushing upwards with the force of a hurricane, and scattering all around fragments of fused rock. Then—although I had said the steam appeared to be pure—we found in the morning the tent was black with ash which had been ejected. Had we remained on the summit only a short time this would not have been noticed. The fragments were found, on microscopical examination, to be particles of fused rock, and they are, I think, torn off by the violence of the steam blasts. This will be found to be of interest in connection with what you will hear subsequently. I attribute these outbursts to the infiltration of the snow and hail which falls on the final cone. It is almost immediately liquified, and descends into the bowels of the mountain. We noticed while on the mountain, that the whole upper part of the cave was white with snow or hail, and yet in the course of an hour or two it would entirely disappear and descend into the mountain. On one occasion, while on the summit, it hailed so violently as to cover us with an inch of ice, and yet in half-an-hour this entirely disappeared.

The height of Cotopaxi is 19,600 ft. Our camp was placed about 130 ft. below the loftiest point, and was the most elevated position at which any of us had ever lived. We remained there 26 consecutive hours, feeling slightly at first the effects of the low pressure, having the same symptoms as we noticed on Chimborazo; and we used chlorate

of potash, and remarked its good effects. All the signs of mountain sickness had passed away before we commenced the descent, and they did not recur again during the journey. Nearly five months later, we found ourselves again on Chimborazo. I desired to make a second ascent for several reasons, but principally because our stay on the summit, on the first occasion, was too brief to permit us to accomplish our work. Besides, the observations of the barometer were somewhat hurried, and I did not feel sure that the deduced heat established a good determination. If, however, a second reading should accord with the first, it would, besides confirming it, establish confidence in respect of observations made in the meanwhile on other mountains. We were too much laden on the first occasion, but now we had trained two natives into respectable mountaineers in order that they might support us. After ascending a peak, we crossed a depression between two mountains, and encamped in a charming spot, surrounded by butterflies and humming-birds. Next day we mounted up to camp five, which was almost 15,000 feet above the others. My time had nearly expired, and we were delighted by a stroke of great good fortune. Next morning was clear and even cloudless, and we saw long before dawn our old friend Cotopaxi in the far distance, and remarked how tranquil it looked—not a sign of smoke was rising from the great volcano. We went on foot, and before daylight, soon commenced to ascend the ridge which leads continuously towards the second summit. I was in the rear, stopping to heat my numbed hands, and looking towards Cotopaxi, when all at once I saw a column of smoke commence to rise from the crater. It went up straight into the air, rapidly curling with such velocity that within a minute it had risen 20,000 feet above the crater. It was caught by an easterly wind, and borne 20 miles towards the east, at right angles, towards its former course; it then turned, and a northerly wind carried it towards our position. As the cloud came nearer and nearer to us, it appeared to rise higher and higher in the sky, and about twelve, at noon, it got overhead, and shut out the sun. But before this happened, we witnessed the most extraordinary and startling effects in the atmosphere between us and the volcano—a thick cloud, sometimes like shining brass, then turned to tarnished copper, or the most extraordinary green, producing a feeling of intense astonishment, which could not be banished. In the curled openings in the clouds that arose after the commencement of the eruption, I still saw a majestic column of ash pouring out, and rising to an immense height in the air, blacker than the deepest ink. As we were engaged in the ascent of Chimborazo, and had many other things to occupy our attention, we did not appreciate at first the magnitude of the eruption, but when we got on the summit, and found the ash beginning to fall to such an extent that the snow looked like a ploughed field, we perceived something out of the common was happening. We arrived on the summit at 20 minutes past 1 on this occasion, and had the satisfaction of finding the end of a flag staff, which had been put up on the first occasion, still appearing above the snow. You will readily believe that I referred to the

barometer with no little eagerness, and read 14.28 in an air temperature of which gave for the height of C 20,489 feet, or 56 feet less than on occasion, the mean of the two deduct 20,517.

When we returned to our tent on October, we found it laden with ash from It was still falling, and covered the ground as with a dense fog. I collected three ounces from the tent, but this was that which was upon it, and much more off down the sloping sides. I subsequently found, in the town of Ambato, nearer the mountain, between 11 o'clock and 11.15, upon a piece of paper spread out, one foot square, four ounces were collected. From these data I have made a calculation of the minimum quantity which must have been ejected, drawing two lines from Cotopaxi leading to Riobamba, 20 miles to the station, and another on a line as far to the north as the limits I am certain this ash at least two million tons of this ash must have been ejected during this eruption. This is under-estimated in a variety of ways: it was carried beyond the limits indicated; I believe it fell over many hundred miles further. The quantity taken into account that actually found on the tent, but from the northwards, that quantity only is referred to fall in a quarter of an hour. Professor Haughton has recently submitted this to my examination and, estimating the weight of the particles, we find the ash which fell on the summit of Cotopaxi was so fine that 4,000 particles scarcely weighed one ounce. That which fell upon it when on Chimborazo was much finer, and in estimating that 25,000 particles go to a grain we are well within the mark. It bears a strong family resemblance to the ash of Vesuvius and consist principally of glassy felspar and long crystalline scoreous dust. It is that which fell on us on the summit was the steam blasts to which allusion has been made, and I conclude that the matter which was ejected during the other eruption was torn off by a continuous blast of almost irresistible violence.

If you can picture to yourselves the quantity of ash required to eject two millions of tons (so light that 25,000 particles scarcely weigh a grain) to a height of four miles in the air from the crater, and to send it up unaffected by the east wind, you may form some idea what a terrible creation it is in his more furious moments.

This, ladies and gentlemen, brings me to a close, and, in conclusion, permit me to say a word more in respect to mountain eruptions in general. Amongst certain persons it is a subject of contempt, for anything in connection with mountain work. None of us feel, I deeply regret the criticism of those who are ignorant of the subjects on which they speak for this matter speaking for myself, I forward to the time, which will surely be the study of mountains, the ascent of them, and even prolonged residence on mo

and essential for the prosecution of a score of men. Before this could be carried out, it was necessary to learn whether life could be made endurable at great heights. We were always haunted by the idea of an invisible enemy who might strike us at any moment. What we wanted to know was, whether life could exist at a height of 20,000 feet; that was settled 75 years ago, by Goy Lussac; whether man could become so far habituated to the pressure which is experienced at that height as to be able to live without inconvenience, and do useful work. I went to the Andes in 1875 to answer to this question, and having the assistance of Mr. Markham, you can form an opinion whether the encouragement for the prosecution of the same in other quarters. There is, I think, no subject of travel more fascinating than mountaineering. Mountains present the grandest of all nature's pictures, they will be always equally beautiful near or far, in cloud or in sunshine; wonderful variety of outline, their startling contrasts of colour, and their dazzling effects, have been a source of inspiration for poets and for artists. They afford perpetual instruction to mountaineers, and they will, no doubt, one day shed light on those great questions touching the origin and distribution of species which have so long exercised the ingenuity of botanists and geologists during recent years. Mountains not only give birth to rivers, have fixed the limits of kingdoms, and have determined the destinies of races; they have often wrecked the hopes of the invader, or sustained the hopes of the defender; they form some of the best material for the peace of the world. So far as mountaineering is concerned, I hold that the exploration of mountains is of the greatest importance for the purposes of political and geological science.

Mr. Markham then proposed a cordial vote of thanks to Mr. Whymper, which was carried unanimously.

## MISCELLANEOUS.

### INTRODUCTION OF CAOUTCHOUC TREES IN INDIA.

Mr. Markham's recently published "Peruvian Rubber" is an appendix on the above subject, and contains other accounts of the following account has been given by Mr. James Collins.

In 1868, a paper appeared in Dr. Seemann's "Botany," on "The Commercial Kinds of Rubber or Caoutchouc," by Mr. Collins. This, for the most part, a résumé of what had been said on the subject, and also contained the recommendations on the preparation and of that article, together with an endeavour to trace the sources of the various varieties.

Mr. P. Le Neve Foster, and the eminent botanist and traveller, Dr. Seemann, the latter article followed up the subject, and the results of his further researches were given in a paper, "India-rubber: Its History, Commerce, and

Supply," read before the Society in December, 1869. The concluding remarks in this paper are as follows:—

"There is one subject which I would more especially recommend to the attention, not only of those present, but also submit to the attention of her Majesty's Government, that is, the acclimatization of the different species of *Hevea* (and also incidentally, I would mention the species of *Isanandra*, which yield gutta-percha) in such of our own eastern possessions, as will be found best suited."

Owing to the prominence thus given, the subject of the introduction into, and cultivation of, caoutchouc trees in India was not allowed to drop, and through the representations of Mr. Markham, Mr. Collins was commissioned to prepare a report on the subject for the Secretary of State for India. This "Report on Caoutchouc" was published in 1872. The following passage from it may be quoted here:—

"The cultivation of economic plants, and the acclimatization in localities where the various conditions, which are so many elements of success, are more controllable than in their native habitat, has a very important bearing on the commerce of a country, and becomes the more necessary for the sustentation and improvement of trade and manufactures, as the march of civilization and colonization or the recklessness of native collectors reduce the area and number of spontaneous forest products. It may be taken as an axiom beyond all controversy, that we cannot long rely on the spontaneous products of the forests, but that recourse must be had, sooner or later, to conservation, cultivation, and acclimatization in order to keep up supplies of all necessary vegetable products."

The recommendations were that the (1) *Hevea*, yielding Para caoutchouc; (2) the *Castilleja*, Central American caoutchouc; (3) the *Vulcan*, Madagascar caoutchouc; (4) the *Landolphia*, African caoutchouc; and (5) the *Urena*, Borneo caoutchouc, should be introduced into India; and that the cultivation of the indigenous *Ficus elastica* should be forthwith attended to. Of the various plants mentioned, the relative values of their products were taken into consideration, the *Hevea* and *Castilleja* being specially mentioned.

These views were adopted, and steps taken to carry them into effect. Meanwhile, Mr. Collins sent out full instructions to a correspondent on the Amazon, and was fortunate enough to obtain seeds of the *Hevea brasiliensis*, and plants raised from these seeds at Kew, were taken by Dr. King to India, in 1873. Thus India obtained her first Para caoutchouc plants. A still larger supply was collected and brought home by Mr. Wickham, in 1876.

Still, not only were seeds and plants to be obtained, but, as was pointed out, there were many questions to be cleared up. Further information was wanted on the physical and climatic conditions under which the trees best flourished, and the best methods of preparing the caoutchouc, &c., and for this purpose observations on the spot were absolutely necessary. In the selection of a proper person, Mr. Markham was so fortunate as to secure the services of Mr. Robert Cross, whose previous travels in search of Cinchona plants, and his knowledge of the country and languages, eminently fitted him for the task.

Mr. Cross left England for Panama Isthmus, in May, 1876, and first searched for *Castilleja* plants, yielding the well-known Central American caoutchouc. The species which he first met with proved to be the *Castilleja Markhamiana*, so named by Mr. Collins in honour of Mr. Markham. This species grows to a height of 160 to 180 feet, with a diameter of about five feet, and a full grown tree yields about 100 lbs. of caoutchouc. The wood is soft and spongy, and rapidly decays. Some caoutchouc prepared from these trees by Mr. Cross was reported to be superior in quality to that yielded by the historic *Castilleja elastica*. The range, too, of these trees

was so wide that in certain districts part of the year is dry. Of the plants collected, 134 flourished at Kew, and of these a goodly supply was forwarded to India in 1876.

Mr. Cross again left England in 1876, this time to procure seeds and plants of the Cearà caoutchouc tree, and further supplies of the Heveas. In both efforts he was successful, resulting in the establishment of 1,000 plants of *Hevea Brasiliensis*, and a goodly number of Cearà plants, all in fine condition at Kew.

The tree yielding Cearà caoutchouc, till this time, was unknown, and to Mr. Cross is due the honour of clearing up its origin. In trying to get up young plants he could not move them, till digging round the roots he found them furnished with tubers of the size and shape of kidney potatoes, and from materials brought home, the plant is recognised as the *Manihot Glaziovii*, a near relative of the tapioca plant. Quotations from Mr. Cross's report on this journey have already been published in this *Journal* (July 12th, 1878), and the report is full of practical information of the utmost cultural value.

Mr. Markham sent the bulk of these plants to Ceylon, from whence, as he says, they can be distributed to suitable spots in India as soon as the Government are less lukewarm on the subject, and fully recognise the importance of the scheme. In Ceylon, the Heveas grow remarkably well, and some trees have reached a height of nearly 30 feet, with a girth of 14 inches. The Castilloas also do equally as well. Later information from Ceylon shows that private planters are taking up the question, and Dr. Trimen, the newly-appointed director of the Peradeniya Gardens has published for their use a series of instructive notes on the cultivation, based on the reports of Messrs. Collins and Cross.

As to Madagascar caoutchouc plants very little information is to hand. Mr. Markham mentions (*Journal of the Society of Arts*, April, 1876) that seeds of *Vaheca* have been sent to India.

With regard to African varieties, Dr. Kirk has displayed much interest, and has procured many plants of the Landolphas. Mr. T. Christy has procured several plants of *Landolphia Florida* and *Urostigma Vogelii*, as well as plants of an apparently new kind from East Africa, yielding an excellent quality of caoutchouc, and some fine and healthy examples of these are now in that gentleman's nursery.

Thus of the various introduced kinds it is pointed out that the Heveas produced the choicest and best caoutchouc, and are well fitted for the moist zones of India. Castilloas will grow over the largest area, and new homes can be found for them in the Western Ghats. Cearà kind thrives on drier ground, and may find a fitting home in the hot dry plains of India.

In the efforts to introduce these exotics into India, the primary recommendation to cultivate and conserve the indigenous *Ficus elastica*, yielding Assam caoutchouc, has not been lost sight of. The first attempts, commenced in 1873, were comparative failures; but since that date the superintendence has been placed under Mr. Gustav Mann, and under his able management the experiment begins now to assume some importance, and, roughly speaking, there are now 1,000 acres in Assam under this cultivation, and the trees are making vigorous and excellent progress.

One other plant deserves notice—a Burmese one—as likely to prove of great utility as a source of caoutchouc. It is the *Chaopannia esculenta*. This plant, of a climbing habit, was always looked upon as a pest by the forest department of British Burma, and every means taken for its extirpation, as it injured the teak trees. Mr. Strettell, one of the officers, however, discovered that it contained caoutchouc, and seems to have proved conclusively that it will repay cultivation. If this turns out to be the case, it will only be another exemplification of the fact, that "a weed is an untitled plant."

Thus, although but yet in its infancy, the subacclimatisation and conservation of caoutchouc trees has arrived at such a stage that its practice is placed beyond all doubt, and the Society congratulates themselves that the warm support to the idea when first brought before them, has an important factor in the present state of affairs must the action of Kew be forgotten. The aid and support given to Mr. Collins by Sir Hooker, and the great care he has bestowed and plants sent to that establishment, have been almost practical moment.

As Mr. Markham says:—"This, if intelligently followed up, will thus ensure future, as the demand increases, a regular supply of the best kinds of caoutchouc from India."

## FRUIT GROWING IN THE UNITED STATES

Consul Cridland, in a recent report, states Florida has very great natural advantages for growing, and especially for the orange and fruits peculiar to warm climates. Large districts situated between the latitudes of 29° 40' north, and longitudes 80° 30' and 82° seem to be particularly adapted to the orange tree, and little else is profitably grown. Formerly, in Florida, as in most of the cotton country, the whole time and attention of the people was in the cultivation of the cotton plant and the sugar cane. Fruit growing was looked upon rather with and no value was attached to the wild orange of the State, any more than to the same quantity of timbered lands. In fact, very frequently the orange trees were cut down and destroyed to make cotton and sugar. Of late years, however, we have found out the importance and profits of fruit culture, and the old wild orange trees are prized, and are converted into sweet orange groves. The difficulty in regard to orange culture is impatience for immediate results. The orange cultivated from the seed, requires from seven years of attention before it begins to bear, and of patience and confidence deters people from an orange grove, and persisting in its care. It has proved that there is no fear of frost in Florida. The quality of the Florida orange is in excellent condition in which it reaches the markets, renders it a most profitable crop. There is no fear of an over-production of the orange when it is considered what a vast quantity can be supplied. In 1879, 4,000,000 dollars' worth of oranges and lemons were imported into the United States, and the orange crop of Florida was at over 1,000,000 dollars. From information published in the United States, it is that the orange crop in Florida next season will be 100,000,000 of oranges, for which the growers will receive 1,500,000 dollars. The crop will double itself every three or four years, considering that the reports to the Government that there are over 20,000,000 of trees in the groves of Florida, in future years the crop will be enormous, and exceedingly profitable, and if the present duty continues, it will stop the export of oranges from Sicily, Spain, and the West Indies. Persons who engage in the cultivation of the orange grove in those parts of Florida where frost is unknown, proceed there and purchase from 1 to 2 acres of land. Suitable land for orange cultivation is from 15 to 20 dollars per acre. The land is then planted, which can be done for 6 dollars per acre. The trees and grubbing the roots, if done the first year, will cost 20 dollars per acre. This work is

to accomplish. Persons are found who under- only to clear, grub, and plough the land, but use the orange trees and set them out. Most purchase and replant trees three years old. 10 to 80 trees are planted per acre; to plant and 300 trees would cost 200 dollars. In two after being set out, which is generally done in or June, the trees are fertilised with guano; and ploughed heavily once a year, and lightly a year. A crop of Southern peas is raised in the trees, and, when ripe, ploughed in to the soil. The trees receive two applications of a year. They grow little the first year; after they become firmly established in the soil, and then there are no serious diseases of the trees in good soil, in Florida. There are a great many orange trees, but none so good as the Florida native trees. In starting an orange grove, it should be cleared of everything, and well spaded. The holes for the orange seedlings should be 3 feet apart, and 18 inches deep, and four feet in diameter. Consul Cridland states that for a total outlay of 100 dollars, a person can have an orange grove in high will, after the fifth or sixth year, begin good income.

#### PEASANT POPULATION OF SERBIA.

The population of Serbia is about 1,750,000, of whom 80 per cent. are peasants, living entirely from agriculture. 10 per cent. of the Servian villages range from 500 inhabitants per village, and 25 per cent. from 500 to 1,000 per village. It follows, therefore, that the peasant population is very much scattered, and the valleys, villages are not widely distant from each other, and it may be divided into two schools, the old and the new. The peasant of the old school cultivates his land in the most primitive manner, whilst the peasant of the new school follows the national system of education, under which he is now to be found in every considerable town advanced on the path of civilisation. The peasant of the old school lives in a cottage with mud walls; his live stock consists of a cow, a half-a-dozen pigs, and a small flock of sheep. His plant comprises a wooden plough, costing about 10s. sterling, a waggon built entirely of a particle of iron entering into the construction of the axles or wheels which cost about three ducats, and a scythe (an axe weighing about 10 lbs.); with the tools the repairs required for the house or half-a-dozen hoes for the maize and the half-a-dozen pruning hooks for the vines; barrels for wine and rakija, and a few earthenware vessels for his goats' and sheep's milk. The oxen draw the plough, and he himself guides it, and all the rest of the field work is done by his daughters. The thrashing of the corn is done thus:—A piece of ground about 40 feet in length is well trodden down, and a large stake is driven in the middle; a pony is borrowed or hired as a labouring carrier, and is attached by a long rope to the stake, the corn in the straw is spread over the ground, and the pony is driven round and round till the cord round the post, he is then driven in the opposite direction till he has unwound the cord, and this is repeated till the corn is thrashed out of the straw. The winnowing is done in a very imperfect, it being done by the peasant with a wooden shovel thrown high up into the air against the wind. The clothing of the peasant of the old school is of his own making, nearly all home-made; his

his wife and daughters spin and weave the cloth of which his shirt, his coat, his "tebakeri" (broad pantaloons), and his stockings are made. His "opantzi" (sandals) are often made by himself, and his winter coat and cap are generally of sheepskins from his own flock. But the peasant of the old school is rapidly being superseded by the modern Servian peasant, who dates back from the year 1832, when Prince Milosh founded at Kragujewatz the first Servian gymnasium, which was followed in 1843 by a General Education Act, under which, and subsequent Acts, education became general and free, no fees of any kind being payable by the pupils. This might, at first sight, appear to have very little connection with agriculture, but education has exercised a very material influence on the Servian peasant; it has improved his mode of life and his method of cultivation, so that he produces more and spends more, thus contributing more to the exports, and raising the imports of the country. The peasant of the new school builds his house of stone or brick, and furnishes it with a view to comfort, if not to luxury; his land is farmed, too, with some regard to scientific principles, his plough is of modern construction, often entirely of iron and steel. His favourite plough is of wood and iron, for 12-inch ploughing, weighing, with the fore carriage, about 130 lbs., and costing at Pesth about five ducats, or £2 10s., but, on account of the difficulty of transport, there being a total absence of railway communication, only 400 to 500 ploughs are imported annually into Servia, and these are to be found chiefly in the vicinity of the Danube. The modern school of peasants understands, too, the advantage of thrashing by machinery, and a hand-thrashing machine of iron and wood, weighing about 450 lbs., and costing about 25 ducats, or £12 10s., at Pesth, is not unfrequently to be found among his plant; as also a hand-winnowing machine, weighing about 300 lbs., and costing about 10 ducats, or £5, and a maize-rasping machine, for separating the maize grains from the stalk, weighing about 200 lbs. and costing about 10 ducats, or £5. But the interior transport difficulty restricts the import of these machines in common with that of all heavy goods. The modern school of peasants, although clinging to the national costume, with regard to pattern and fashion, is rapidly adopting Western woollen and cotton manufactures as the materials for his clothing, and that of his wife and family, and this fact cannot fail to have a large and increasing influence on the import of woollen and cotton textile manufactures into Servia.

#### PLANT-LABELS.

The Rev. C. Wolley Dod, of Edge-hall, Malpas, writes to the *Gardeners' Chronicle*, as follows:—

"On going round the herbaceous garden at Kew, it has often occurred to me that the labels are taken up and laid together every time a bed is raked, and afterwards replaced by the labourer from memory, the evident transpositions having seemed difficult to explain in any other way. But after the experience of this winter, when nearly all our flat wooden labels are not only out of the ground, but appear to have been shot out, something in the way in which I have seen porcupines at the Zoological Gardens shoot out their loose quills, so as to be at a distance from the plant which they marked, any amount of demoralisation in the naming of mixed borders can be easily understood. Hence the subject of labels is not unnaturally attracting a good deal of attention at present.

"It may help those of inventive genius who are going to compete for the prize for the best plant-label offered by Mr. G. F. Wilson, through the Society of Arts, if hints are sent by those who have tried different

kinds of labels, so as to give the competitors the full benefit of all past experience. I assume that in all mixed collections of plants a large number of labels is necessary. In my garden, which is of moderate size, I label nothing which can be recognised at all times of the year without a label, and yet I have fully 10,000 labels in constant use. Labels should be (1) cheap, (2) durable, (3) indelible, (4) portable, (5) markable with a common lead-pencil, (6) not liable to be ejected by frost, or (7) broken by a kick.

"Those who have plenty of hazel trees at hand will find hazel rods, three quarters of an inch in diameter, cut into lengths of about 10 inches, with an horizontal slice cutting into 4 inches from the upper end, and made by a single cut of a knife, to take the paint for writing, in many ways better and cheaper than the common flat labels. They last three times as long, or more if the lower end is dipped in creosote. A common labourer with plenty of material, using a pair of pruning-shears and a strong sharp knife, will easily cut 1,000 in a day, and they possess qualities 4, 5, 6, and 7.

I have, however, invented and adopted another label—clumsy I admit, and not readily commending itself to others, but far more simple in practice than it sounds in description. It reminds me of the military regulation order explaining the cooking of a musket, or printed directions given for learning to swim. What reads and sounds as if it were difficult and complicated, becomes in practice the simplest thing in the world. Common round bar-iron, three-eighths of an inch in diameter, is cut obliquely into lengths of 10 inches, and pierced with an eye  $\frac{1}{2}$  inch from one end, and dipped when red-hot into gas-tar. For these pegs, which weigh about 4 oz., I pay 60s. per 1,000, but think they might be had for less. Then I have flat wooden suspending labels pierced at each end, for which I pay 4s. 6d. per 1,000; through the two eyes 6 inches of pliant wire is passed, for fastening the label to the iron pin. These are, upon the whole, the most satisfactory labels I have yet used. They cost 5s. 6d. per 100, but the iron pin—nine-tenths of the cost—is indestructible. The label is easily and quickly renewed, and will last, when suspended, for many years. Not one has been ejected from the ground this winter, and if kicked over they are not hurt, and easily set up again. It is true they are heavy to carry about, but I keep a stock of the pins, which are weather-proof, in various corners, so as to have them handy for all parts of the garden.

"Then the wired labels are just as portable and as easily written on as common flat wooden pegs. My great desideratum is a white paint which will reject the splashing of mud, but retain for ever the writing of a lead-pencil. I can get no paint which is perfectly smooth and not sticky when dry, and should be thankful to be told of any. I enclose specimens of what I have described.

"I may add that a heavy plant-label is not altogether without its advantages. In the year 1842, when I was a boy at Eton, one of the many jackdaws which built in the college chapel insisted upon having her nest so arranged that she could, whilst sitting, see out of the turret loophole, which looked towards Windsor Castle. This could only be done by making the foundation on a step of the spiral staircase, nine feet below; and a massive nest, nine feet high, was accordingly built. I made friends with the college clerk, and watched the progress of the nest, and recollect that amongst the materials, besides there being a box of lucifer-matches, garden pegs seemed to be in great request. Three or four years later, when I was at Cambridge, I recollect the present Professor of Botany exhibiting, at a meeting of the Ray Club, a newly-devised label for use in the Botanic Garden there. It was a very heavy metal one—the weight, he said, being found necessary to prevent the jackdaws carrying them up for their nests between the roofs of King's College Chapel."

## NOTES ON BOOKS.

**Electro-typing.** By J. W. Urehart. (London: Wood and Co., 1881.)

This book is of a similar character to the manuals which have been issued by the Society of the practical applications of electricity throughout is to make himself intelligent who have not much knowledge of science. Chapters deal with the metals employed in electricity, describing not only the but also some of the machines now so largely employed for electro-plating purposes. Electro-type setting, moulding materials, &c. in succession, while the concluding chapter deals with the preparation of the work as treating it after the electro-type process.

**The Expiring Continent.** By A. W. (London: W. H. Allen and Co.,

Under this title Mr. Mitchinson gives his travels in Senegambia. Mr. Mitchinson time travelling in that country and among people, so that he was in a position to take notes of the manners and customs and of the natural productions of the country which he travelled. As was the case in the book read before the Society last year on "Causes of Disease in Tropical Countries," Mr. Mitchinson devoted considerable attention to man and frequent observations upon them in the work. The book has a number of illustrations and also contains a map of the districts traversed.

**Water: its Composition, Collection, and a Practical Hand-book for domestic use.** By Joseph Parry. (London, F. Warne

The subjects of the chapters into which the book is divided are, the composition of water, supply, purification, modern waterworks, waste, rural supplies, domestic supplies, purposes, and regulations for the preservation and misuse of water. Chapter 6 contains water rents, rates, and charges, with a table charged per annum for domestic supply in towns of Great Britain.

**The Wild Silks of India, principally Tusser.** Wardle, F.C.S. (London, Eyre and 1880).

This is a reprint by the Government of a paper, read before the Society of Arts, the *Journal* for May 9, 1879.

## OBITUARY.

**Professor Tennant, F.R.S.**—By the death of Professor Tennant, on the 24th of February last, seventy-three years, the Society of Arts and active member. Mr. Tennant was and afterwards the successor, of J. M. "Travels in Brazil," and of a "Treatise" whose original series of minerals forms the large collection of mineralogical specimens, and fossil remains Tennant eventually gathered together. He also possessed a rich collection of minerals of which the Devonshire collection forms

He was, for many years, Professor of Geology and Mineralogy at King's College, London, and after the Professorship of Geology he retained the

Professor of Mineralogy, which he held at the time of his death. In conjunction with the late Professor of Geology and the Rev. W. O. Mitchell, he wrote the "Treatise on Geology, Mineralogy, and Logography" for "Orr's Circle of the Sciences," and is also the author of descriptive catalogues of and of popular lectures on the sciences in which he was specially interested. Mr. Tennant was an active member of the Turners' Company, and took interest in the action of that company for extending Technical Education. He was elected a member of the Society of Arts in 1846, was a constant attendant at its meetings, and frequently joined in the discussions, reading a paper on "South African Diamonds," on November 23, 1870.

## GENERAL NOTES.

**Extinction.**—A public exhibition of Dick's "Steam-tour," and brigade chemical fire-engine, "Excel," was held on Tuesday, 8th inst., on a piece of large ground in Whitehall-place. A fire of wood saturated with kerosene was lighted, and then immediately extinguished by these engines.

**Sanitary Assurance.**—Dr. F. de Chaumont, F.R.S., gave a lecture on "Sanitary Assurance" at the Institution, Finsbury-circus, on Tuesday, March 3 p.m., in connection with the Sanitary Assurance Association. The chair will be taken by J. Eric Erichsen, President of the Royal College of Surgeons. Members of the Society of Arts will be admitted to the lecture without showing their cards.

**Spanish Fine Art Exhibition.**—It is proposed to hold a Spanish Fine Art Exhibition at Madrid, to which Spanish artists may alike contribute. Works belonging to the following categories, which have received the sanction of the jury, will be admitted:—(1) Paintings, in oil, water-colour, stained glass, lithographs, wood engravings, and drawings; (2) Sculpture; (3) Architecture; (4) All other works, although not expressly included under any of the foregoing headings, may be considered by the jury, on the ground of their artistic merit, worthy of a place in the Exhibition. Works by deceased artists will not be admitted. The Exhibition will be held at intervals of three months, commencing in the month of April. Each exhibitor may present a limited number of works of each class. There will be a special room in the Exhibition set apart for those works which have not been accepted by the jury, but whose authors are, nevertheless, desirous of exhibiting them to the public. Information can be obtained by intending exhibitors at the Spanish Legation, 12, Queen's-gate-place, S.W.

**Edinburgh School of Cookery.**—The fifth annual meeting of the Edinburgh School of Cookery was held at the school, Shandwick-place, Lord Provost presiding. The Secretary (Miss Guthrie Wright) read the annual report of the Executive Committee, from which it appears that, during the session 1879-80, the usual courses of instruction in high-class, plain, cheap, and sick-room cookery were given in the school. Classes were held at various institutions and schools, and two demonstrations on sick-room cookery to medical students, in the room, Minto-house. In addition to the ordinary instruction, the following have received instruction in the School of Cookery and Domestic Economy:—Thirty-one nurses from the Royal Infirmary; eleven girls from the Minto House; seven girls from Young-street School; public classes were, on application, given in Leven and Portobello. In developing the institution into a school of domestic economy, the committee aim chiefly at providing instruction as will render women efficient and useful in the home. The funds show an income during the year of £1,740 17s. 4d. of funds in balances brought from the previous year. The expenditure has been £244 4s. 9d., leaving funds and income on hand of £1,496 12s. 5d.

**Royal Albert Hall.**—The annual general meeting of the members of the Royal Albert Hall Corporation was held on Saturday, 26th February, at the hall, South Kensington, the Right Hon. Lyon Playfair, M.P., in the chair. The Chairman, in moving the adoption of the report, said it was gratifying to the council to have been able to reduce the hall debt by £1,190, although this had been accomplished rather through the kindness of their creditors than any surplus of money in hand. Messrs. Burchell, their solicitors, having taken six seats at the par value of £100, which was much more than their selling value. They would again find it necessary to ask for a seat-rate of £2 for the current year. They were keeping the hall in a very efficient state of repair, but the profits of the hall had not yet enabled them to dispense with that rate. During the year they had an exhibition of fine arts, and its success justified them in recommending another exhibition in the present year. The Council of the Society of Arts also proposed, in connection with the fine art exhibition, to have an art industrial exhibition, and invited art workmen, manufacturers, and others to submit such works in all materials. The formation of a road between the Kensington and Exhibition roads would increase the facilities of access to the eastern entrances of the hall, but even then the approaches would not be all that the council could desire with the view of increasing the attendance at the hall. The system of lighting the hall by electricity had been experimented upon during the year by Messrs. Siemens Brothers, without cost to the corporation. Messrs. Siemens had repurchased part of the apparatus for £310, and as this means of lighting became more perfected they hoped, with the machinery they had retained, to be able to adopt it at a trifling cost. Mr. G. Godwin, in seconding the motion for the adoption of the report, stated that the council would be very glad if the members interested the outside public and the seaholders in the success of the exhibition organised by the Society of Arts. Sir Henry Cole observed with regard to the fine art exhibition that it would probably include a large number of pictures which the Royal Academy had intimated they would have accepted had there been room. The report was unanimously adopted, and subsequently resolutions were passed requesting the Prince of Wales to act as president of the hall, and re-electing the retiring members of the council.

## THE LIBRARY.

The following works have been presented to the Library:—

Some Particulars with reference to the Concession for the Construction of the Great Andino-Argentine Railway, from Mercedes to Mendoza and San Juan. (London, 1879.) Presented by Mateo Clark.

Solutions of the Questions in Magnetism and Electricity, set at the Preliminary Scientific and First B.Sc. Pass Examinations of the University of London, from 1860 to 1879, by F. W. Levander, F.R.A.S. (London: H. K. Lewis, 1880.) Presented by the publishers.

The Signature of Gutenberg, by P. de Villiers, M.D. (London: Kerby and Endean.) Presented by the author.

Hastings as a Health Resort, by P. de Villiers, M.D. (Hastings, 1879.) Presented by the author.

Water: its Composition, Collection, and Distribution, by Joseph Parry, C.E. (London: Frederick Warne and Co., 1881.) Presented by the publishers.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MARCH 16.—"The Beaumont Compressed-Air Locomotive." By Col. F. BEAUMONT, R.E.

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Cause." By CORNELIUS WALFORD.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. FREER.

APRIL 6.—"The Discrimination and Artistic Use of Precious Stones." By Professor A. H. CHURCH, F.C.S.  
 APRIL 27.—"Five Years' Experience of the Working of the Trade Marks' Registration Acts." By EDMUND JOHNSON.

Dates not yet fixed:—

"The Manufacture of Glass for Decorative Purposes." By H. J. POWELL (Whitefriars Glass Works).  
 "Buying and Selling; its Nature and its Tools." By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.  
 "The Electrical Railway, and the Transmission of Power by Electricity." By ALEXANDER SIEMENS.

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MARCH 15.—"Diamond Fields of South Africa." By R. W. MURRAY.  
 APRIL 5.—"Canada; the Old Colony and the New Dominion." By E. HEPPLE HALL.  
 MAY 10.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MARCH 24.—"The Future Development of Electrical Appliances." By Prof. JOHN PERRY.  
 MAY 12.—"Recent Progress in the Manufacture and Applications of Steel." By Professor A. K. HUNTINGTON.

#### INDIAN SECTION.

Friday evenings, at eight o'clock:—

MARCH 25.—"The Tenure and Cultivation of Land in India." By Sir GEORGE CAMPBELL, K.C.S.I., M.P.  
 MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

#### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Third Course will be on "The Scientific Principles involved in Electric Lighting," by Prof. W. G. ADAMS, F.R.S. Four Lectures.

#### Syllabus of the Course.

##### LECTURE II.—MARCH 14.

The measurement of electric currents. Efficiency of magneto- and dynamo-electric machines. Heating effects of the current.

##### LECTURE III.—MARCH 21.

Use of magneto- and dynamo-electric machines for electric lighting. Electric lighting by means of the arc.

##### LECTURE IV.—MARCH 28.

Subdivisions of the electric current. Incandescent lamps. Luminous effects of electric currents in a vacuum, and in various gases.

#### MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 14TH.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Professor W. G. Adams, "The Scientific Principles Involved in Electric Lighting." (Lecture II.)  
 BRITISH HOROLOGICAL INSTITUTE, Northampton-square, E.C., 7 p.m. Mr. John Standfield, "Cheap Patents and Prosperity."  
 ROYAL GEOGRAPHICAL, University of London, Burlington-gardens, W., 8½ p.m. Mr. James Stewart, "Lake Nyman and the Water-route to the Lake Region of Africa."  
 ARTISTS' ARCHITECTS, 3, Conduit-street, W., 8 p.m. Special General Meeting to elect Royal Gold Medallist, and to receive Council Report on Medals.

Medical, 11, Chandos-street, W., 8½ p.m.  
 LONDON INSTITUTION, Finsbury-circus, E.  
 G. Phillips Bevan, "The Gold and Silver World."  
 TUESDAY, MARCH 15TH.—SOCIETY OF ART, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.)  
 Mr. R. W. Murray, "The Diamond Africa."

ROYAL INSTITUTION, Albemarle-street, W., 8 p.m.  
 A. Schäfer, "The Blood." (Lecture D)  
 CIVIL ENGINEERS, 25, Great George-street, S.W., 8 p.m. 1. Renewed discussion of Thomson's paper on his "Tide-gauge, Analyser, and Tide Predictor." 2. Mr. "The Comparative Endurance of Iron when exposed to Corrosive Influences." Statistical, Somerset-house-terrace, Strand, Mr. Hyde Clarke, "The Progress of Stations in the Hill Regions of India." Pathological, 53, Berners-street, Oxford-street, Zoological, 11, Hanover-square, W., 8½ p.m.  
 WEDNESDAY, MARCH 16TH.—SOCIETY OF ART, Adelphi, W.C., 8 p.m. Colonel F. B. Beaumont Compressed-Air Locomotive Meteorological, 25, Great George-street, 1. "Exhibition of Hygrometers and Meteorological and other Instruments brought out since January 1st, 1880." Sketch of the different classes of Hygro-thermometers, who will also describe such exhibited.

PUBLIC ANALYSTS, Burlington-house, W., 8 p.m. 1. "The Swedish Acts for the regulation of Poisons." 2. Mr. Bernard Dyer, "of Milk." 3. Mr. J. West Knights, "for the Estimation of Nitrates in Potatoes." 4. Mr. J. Carter Bell, "Samples of Milk water below the Society's Standard." ARCHAEOLOGICAL ASSOCIATION, 33, Sackville-street, 1. Dr. James Stevens, "Recent Discoveries." 2. Mr. Henry Frigg, "Roman Pottery Stow." ROYAL COLLEGE OF PHYSICIANS, Pall-mall E (Gulstonian Lecture.) Dr. Couplan (Lecture II.) BRITISH HOROLOGICAL INSTITUTE, Northampton-square, W., 8 p.m. Mr. Curzon, "The Lever and the correct Principles and common Faults."

THURSDAY, MARCH 17TH.—ROYAL, Burlington-house, W., 8½ p.m. Antiquaries, Burlington-house, W., 8 p.m. Linnean, Burlington-house, W., 8 p.m. Watt, "The Indian Species of *Prunella* Boeg Watson, "Mollusca of *Challenger*." 3. Mr. B. Daydon Jackson, "Note on *E. Linn.*, and Certain Allied Species." Chemical, Burlington-house, W., 8 p.m. Brown, "The Volumes of Mixed Liquors." 3. Mr. F. J. Edgar Wilcock, "The Action of Aldehyde thraquinone in Presence of Ammonia Jupp and Mr. H. J. N. Miller, "The Acid on Napthaquinone." 5. Mr. R. V. Alleged Formation of Nitrous Acid in the presence of Water." 6. Prof. Hartley, "of Solar Rays by Atmospheric Ozone in the Tint of the Atmosphere." 7. Mr. C. F. Mr. E. H. Rennie, "Note on the Swallow *Glycyphylia*."

LONDON INSTITUTION, Finsbury-circus, E., 8 p.m. W. H. Stone, "The Combination of Volcanoes" (with illustrations). ROYAL INSTITUTION, Albemarle-street, W., 8 p.m. Statham, "Ornament Historically considered." (Lecture I.) ROYAL HISTORICAL, 11, Chandos-street, W., 8 p.m. Numismatic, 4, St. Martin's-place, W., 8 p.m. Philosophical Club, Willis's-rooms, St. James's, 8 p.m. CIVIL AND MECHANICAL ENGINEERS, 7, Westmoreland-street, W., 7 p.m. Mr. R. E. Middleton, "and Sewerage." ROYAL NATIONAL LIFEBOAT INSTITUTION, Meeting at Willis's Rooms, St. James's, 8 p.m. FRIDAY, MARCH 18TH.—ROYAL COLLEGE OF PHYSICIANS, 11, Chandos-street, W., 8 p.m. (Gulstonian Lecture.) "Anemia." (Lecture III.) ROYAL UNITED SERVICE INSTITUTION, Whitehall, 8 p.m. Captain C. W. B. Bell, "The Cavalry; its Screening, and Outpost Duties." ROYAL INSTITUTION, Albemarle-street, W., 8 p.m. H. Stone, "Musical Pitch and its Determination." Philological, University College, W.C., 8 p.m. Postgate, "Latin and Greek Derivatives." SATURDAY, MARCH 19TH.—LADIES' SANITARY ASSOCIATION, 11, Chandos-street, W., 8 p.m. Richardson, "Domestic Sanitation" (Lecture V.) ROYAL INSTITUTION, Albemarle-street, W., 8 p.m. B. Hawcis, "American Humors."

## OF THE SOCIETY OF ARTS.

No. 1,478. Vol. XXIX.

DAY, MARCH 18, 1881.

as for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## NOTICES.

## CANTOR LECTURES.

A lecture of the third course was Monday, 14th inst., by Professor W. R.S., on "The Scientific Principles of Electric Lighting." The subjects dealt with in the lecture were the uses of electric currents, the efficiency of the dynamo-electric machines, and the effects of the current. These were illustrated by a series of experiments. The lectures were held during the summer vacation.

## ALBERT MEDAL.

It will proceed to consider the award of the Medal for 1881, early in May next. It was struck to reward "distinguished services rendered to Arts, Manufactures, or Commerce" has been awarded as follows:—

Sir Rowland Hill, K.C.B., F.R.S., "for his services to Arts, Manufactures, and Commerce by the creation of the penny postage, and for his improvements in the postal system of this country, which have, however, not been confined to England, but have extended over the civilised world."

His Imperial Majesty, Napoleon III., "for his merit in promoting, in many ways, by his patronage, the international progress of Arts, Manufactures, and Commerce, the proofs of which are the judicious patronage of Art, his enlightened policy, and especially, by the abolition of the duties on the importation of works of art in favour of British subjects."

Professor Faraday, D.C.L., F.R.S., "for his services to Arts, Manufactures, and Commerce by his researches in electricity, magnetism, and chemistry, and for his promotion of the industries of the world, by his inventions and discoveries."

Mr. (afterwards Sir) W. Fothergill Cooke (afterwards Sir) Charles Wheatstone, "for their joint labours in establishing the electric telegraph."

Mr. (now Sir) Joseph Whitworth, F.R.S.,

LL.D., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Ferdinand de Lesseps, "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (now Sir) Henry Cole, C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the development of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1873, to C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with the economisation of fuel in its various applications to the Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential service in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy, and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S., "on account of the signal services rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science and industrial pursuits."

The Council invite members of the Society to forward to the Secretary, on or before the 23rd of April, the names of such men of high distinction as they may think worthy of this honour.

**LABEL FOR PLANTS.**

The Council are prepared to award a Society's Silver Medal, together with a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award.

Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of withholding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

**PROCEEDINGS OF THE SOCIETY.****FOREIGN AND COLONIAL SECTION.**

Tuesday, March 15th, 1881; HARRY ESCOMBE, Member of the Legislative Council of Natal, in the chair.

The paper read was on—

**DIAMOND FIELDS OF SOUTH AFRICA.**

By R. W. Murray.

Seeing how little is known of South Africa, its people, and natural resources here in England, and how much this country, as well as its rich and vast colonial dependency, has lost, and is still losing, through the lack of such knowledge, it becomes the duty of every man who is informed upon South Africa, its public affairs, its soil, climate, resources, and people, to impart all the information upon these that he can whenever a suitable opportunity presents itself.

Few men who have made themselves thoroughly acquainted with South Africa, whatever opinions they held before visiting it, but are convinced that it is destined to become a great country—English colonists hope, a most important portion of the British Empire.

It is not long since you heard from Sir Bartle Frere, in this very room, how rich and varied are the industrial resources of South Africa. That gifted lecturer has, since his return to England, devoted himself most arduously to his self-imposed task of making South Africa better known to his fellow-countrymen, and to him the people of South Africa will feel more than ever attached, if that be possible, when they come to see how much he has done for them upon English platforms.

I am not about to lecture on the general characteristics of South Africa, but to bring, as far as I can, into the prominent notice it deserves to have, that part of the South African continent in which I have

spent the last ten of the twenty—  
have been in the country.

Whilst very little is known in England of the portion of South Africa, the Diamond Fields, at least known, and have, I think, been presented, and yet no single spot of ground in the whole world is better worth knowing than these. I have held, and still hold, that of modern times is more remarkable than the Diamond Fields of South Africa; and her Majesty's dominions has made such progress in civilisation and wealth, and the progress of the province of Griqualand, in which the Diamond Fields are situated, by misgovernment, it will be one of the chief centres, if not the chief centre, of commerce in that great country.

I shall not weary you with any speculations regarding the formation of the Diamond Fields, or take up any of the time allotted to me in introducing any of the questions regarding geological formations of this territory from time to time, been discussed in the world. I shall but a plain, unvarnished statement of its history, from the time of its discovery to the present hour, endeavouring to show how vastly it has contributed to the progress of the world, how much it is still contributing to, and in what an extraordinary manner it has been civilising the native tribes of the country. The most important part it has played in the history of South Africa during the last ten years.

In the first place, as to the Diamond Fields, it is necessary to mention that in 1867, the Cape Colony and Natal were most acutely from financial and depression. The Free State had had to fight against its native neighbours, the Basutos, and its indebtedness to the Cape Colony and Natal had hardly come to be of any worth to colonial credit. A general bankruptcy throughout South Africa appeared inevitable.

The public works which had been started by the Cape Parliament had been stopped; the engineers and navvies, from England for railway construction, were most of them, out of employ. The merchants in Cape Town, Port Elizabeth, Grahamstown, and the other principal centres of trade, as well as those of the interior, glutted with stocks, which were not wanted, were off. The life of South Africa appeared gone out of it. The farmers had run down their estates, until, one after the other, they were well-to-do, went into the *Gazette*, and was the state of affairs in the western portion of the Cape Colony, that many a man who was a producer of cereals all his life, had to go to the mill for meal for his family use.

The chief cause of this dire distress was the long series of droughts to which the country had been subjected. So bad were the things, and so helpless had everybody become, that many families, who could come to the coast enough to pay their passages, left the interior for the other shores.

In the course of that year, 1867, just when things were at the very worst, and men began to regard the whole of South Africa as a

Mr. John O'Reilly, a trader and hunter in the interior, was in Albania. Here I had better explain that Albania is a portion of the province of Griqualand West. It was a portion of the territory of the Griquas, who were under the chieftainship of Nicholas Waterboer, who afterwards ceded his territory to the British authorities. That territory, which became a Crown colony, and in which are the diamond diggings and mines, is situated between the Cape Colony, the Free State, the Batlapin territory, and that which is set down in the old maps as occupied by Hottentot tribes, and in which the copper mines are found. I shall endeavour to amuse and amaze you with more of such details than are unavoidable. The latitude and longitude are not at all essential to the subject with which I am dealing. It will be sufficient for you if I state that Griqualand West is about 600 miles from each of the ports, and that it is approached by various routes; those most frequented are the western, or the Bay route, the eastern, from Port Elizabeth, the Frontier, or the East London route, and the Cape or Natal route.

Albania, of which I commenced to speak, was a portion of the Griqua territory, settled by colonists under terms made with Waterboer, some two years before the discovery of diamonds had been made. One of the colonists who had helped to the settlement was a Mr. Van Niekirk. Mr. O'Reilly, who was returning from the interior to the port, called upon Van Niekirk, and remained with him the night. In the course of the evening, one of Van Niekirk's children, a little girl, was playing on the floor with some of the pretty stones which are common in the neighbourhood of the Vaal River. Mr. O'Reilly's attention was directed to one of the stones, which threw out a strong light, to which Mr. O'Reilly's eyes had not been accustomed. He took it up from the floor and asked to buy it, asking what Van Niekirk would take for it. The simple-minded Boer could not make to understand what the meaning of buying a stone could be, and he said he would not take money for it, but that if Mr. O'Reilly had asked for it, he could have it.

A colonial trader is generally represented as a man of a most designing and unscrupulous character, but there are men amongst them whose right mind and high character would stand comparison with those of any men in the world, and no men better footing amongst the Boers than the established traders. Mr. O'Reilly is one of these.

He told Van Niekirk that he believed it to be a precious stone, and of value; he would, he said, not take it for nothing. It was ultimately agreed between them that O'Reilly should buy the stone, ascertain its value, and, if found to be a diamond, as O'Reilly suspected it was, that it should be sold, and the money divided between them.

Mr. O'Reilly took the stone to Colesberg, where he showed it, and he confidently stated to the people he met at the bar of the hotel that it was a diamond. He wrote his initials on the stone, and cut a tumbler with the stone, and was laughed at for his alleged foolishness, and that he was a discoverer had been before him. One day a company took the stone out of O'Reilly's pocket and threw it into the street. It was a narrow street, and the stone was found again, and, had it not been, it is quite a question whether the Diamond

Fields of South Africa had yet or ever been discovered in our day. However, the stone was found, and O'Reilly sent it to Grahamstown, to Dr. Atherstone, to be tested, and the doctor and Bishop Richards, the Roman Catholic Bishop of Grahamstown (one of the most scientific men in South Africa) both pronounced it to be a diamond of 22½ carats. From Grahamstown the stone was sent to the then Colonial Secretary, the Hon. Richard Southey, afterwards the Lieutenant-Governor of Griqualand West, who submitted the stone to the best authorities at hand, and they all decided it to be a diamond. It was then forwarded to the Queen's jewellers, Messrs. Hunt and Roskell, who confirmed the decisions obtained in the colony, and valued the stone at £500. At this valuation, it was purchased by his Excellency, Sir Philip Wodehouse, who was Governor of the colony at the time. Mr. O'Reilly, as soon as he had ascertained for certain that his first stone was a diamond, set out to see if he could not find others, and was not long before he found one of 8 carats and ¾, and this too was purchased by Sir Philip Wodehouse for £200. This led to a good deal of excitement throughout the country. Small diamonds were brought in by natives. Then flashed the startling intelligence through the country, that a diamond of over 83 carats had been discovered. This turned out to be true, and this is how it came about. Mr. Van Niekirk, from whom Mr. O'Reilly obtained the first stone, hearing that it had turned out to be a diamond, remembered that he had seen one of a similar character in the possession of a native, and set out to find it. A Boer is not long in getting hold of a native when he wants him, and Van Niekirk soon had his man. The native had kept the stone, and Van Niekirk gave him nearly all he possessed for it—about 500 sheep, horses, &c.—but at whatever the price, he obtained the stone, and set off with it to Messrs. Lilienfield Brothers, of Hopetown, merchants of long standing in South Africa, and now represented in Hatton-garden. They purchased the stone for £11,200, and christened it "The Star of South Africa," forwarded it to England, and it ultimately became the property of the Countess of Dudley, who purchased it of Messrs. Hunt and Roskell.

That all this would have a great effect upon communities, whatever their conditions and prospects in life, no one will have the least difficulty in believing, but the excitement it did create amongst the various communities of South Africa, who were at that period on the verge of bankruptcy, it would be difficult to convey to you. It is said that drowning men catch at straws, and I have no doubt that that proverb is well founded. But it is one thing for a drowning man to catch at a straw in his last extremity, and another for him to be inspired by faith to rise and walk upon the water. The people, who almost despaired of the country or themselves being restored to prosperity again, wanted to see the prints of the diamonds on the hill-sides from which they had been taken. They did not deny that the diamonds had come to Cape Town, nor that they had been sent to England, nor that they had been sold for much money. Some had seen the diamonds, others had seen men who had seen them, and, besides, Sir Philip Wodehouse had purchased two and paid his money for them, and the word of Sir Philip Wodehouse was at that time a

law unto all South Africa. Where did the diamonds originally come from? That was what they wished to know. They were out of love with the Cape, and it was with the old colony as it was with Nazareth, men shook their heads and asked each other "Can any good come out of it."

They at first, of course, denied that there were any diamonds. Then, when they could do that no longer, they said that they had not been found in South Africa. At last, they not only thought, but said, that the whole thing was a plot of the Hope Town and Colesberg owners of land to send up the price of their land, and that they had imported the diamonds from the Brazils. What wonder that this should be said, when an authority on such matters, who was sent out by one of the first dealers in precious stones in the known world to spy out the land, after making a tour through it, and a scientific survey of it, reported most dogmatically that there could be no diamonds found in the country, and gave his "reasons why." A letter appeared in one of the leading journals, duly signed by this great authority in diamonds, in which the writer settled, to the satisfaction of those who previously doubted the validity of the diamond finds, that South Africa was non-diamondiferous.

What do we not get settled for us by authorities in the leading journals? Alas! for some of the authorities, the result of their settling affairs of politics, sciences, and art is much the same as in the case in point. Whilst the print was fresh which conveyed the decision to the world that no diamonds could ever be found in South Africa, intelligence arrived in England that good parcels of diamonds had been secured by several well-known persons.

At the end of 1868, the more enterprising of the colonists pushed their way up to the Vaal River, where it was supposed the diamonds had been found. There has always been much discussion as to who were the first in the field. I have taken pains to discover, and I think there can be no doubt that the first party who went up from the colony to search for diamonds was formed in Bethulie, headed by the late Mayor of Kimberley, Mr. J. B. Robinson, and that the next came from Natal, the men of which colony have always been famed for their enterprising character. It was not, however, until about Christmas, 1869, that the general movement commenced, and, at that time, a party from King Williamstown (British Kaffraria) passed through the Free State. They made no secret as to their destination or purpose, and were thoroughly ridiculed when they said they were going to search for diamonds along the banks of the Vaal River. When the Bethulie party first arrived, they had no idea of digging for diamonds; they considered, like many other people, that diamonds fell "like the gentle dew from heaven upon the earth beneath."

When they arrived, they found on the banks of the Vaal, half-way between the Berlin Missionary Station and a place called Hebron, where the first diggings were established, a native who had a diamond in his possession. He had heard that it might be a diamond, and he had wrapped it up in several dirty bits of rag, and tied it up, but he never suspected that he was to get eight golden sovereigns for it as he did. Of course, the rumour that such stones were worth so many sovereigns

soon got noised abroad, for the first thin native who had all this money did, was to jollification to his sisters, and his cousin uncles, and his aunts, and the jollification over some ten days, brought together (chiefly Koranas) from far and near. They were set looking for diamonds along the banks of the hills, and they found well. Some hundreds were soon at this work, and the party sent into the colony, realised their party and brought Basutos up to work expressly. The party settled on a farm then, Livingstonia, near Hebron.

No thought of digging for diamonds appears to have occurred to any one until the arrival of a party from Natal, one of whom had been a digger in California and Australia. His idea was to sink a shaft; that, however, was a failure, the digging out of the diamondiferous soil, cradling it for diamonds, just as in gold-mining was adopted, and the principle of which obtained to this day.

Whilst the parties I have mentioned were settling on the banks of the Vaal near Hebron, a Kaffrarian party crossed the Vaal lower down, and settled themselves at a place called Klipdrift, where they picked up diamonds too. They, finding that there was a party up the river as well, went up there, and, by the time they reached Hebron, they found that other parties came from Natal, and others were on their way. In a month or two after, there were hundreds of wagons loaded with diamonds on their way from all parts of South Africa, for the Vaal River. At the first, all the diggings were found on the side of the river furthest from the Cape Colony. About the middle of 1870 a large number of wagons of colonial Boer colonists arrived at Pniel, which is the name of a place on the colonial side of the river, and the Boer colonists to whom the wagons belonged, discovering that the river was "down"—which means it was too deep to be crossed—outspanned there as the river remained unfordable for over a night, some of the Boers and others thought they would dig, and see if there were no diamonds to be found on that side of the river as well as on the other. They did so, and were soon rewarded with diamonds, which they—at the time, not knowing anything about cradling—picked out of the river which they dug up. But for the Vaal River being unfordable, the Pniel diggings might have been discovered. The majority of those who had outspanned at Pniel never crossed the river to Klipdrift to dig, but remained where they were, and a camp was formed there. This was the beginning of the famous Pniel Diggings, out of which hundreds and hundreds of men made their money. Klipdrift was at the time considered no more than a small land; the chief, Jantje a Koranna, was supposed to have the most right to it, and he himself told the diggers that that territory belonged to him, and he took a good deal of money for it from the diggers which, of course, they never gave. On the Klipdrift side no money was paid for the right to dig. Pniel was and is the property of the Berlin Missionaries, held under a grant from the Free State Government. Ten shillings a day was paid for digging there, and that money, the diggers paid it, the Berlin Missionaries received.

wholly or in part—I am not sure which. In September, 1870, the Pniel camp had become a canvas town, as a matter of course, and Klipdrift side a canvas town had also sprung up in 1870, there could not have been less than 2000 men at work on the Pniel side of the river, and 500 on the Klipdrift side; Hebron was as

many diamonds were found, but it is a question whether, up to September, 1870, the fields gave a profit on the outlay expended on them. A good many men had made money out of the diamonds they found, for the price then paid was greatly in excess of the price which diamonds now realise. I shall go on to outline the history of the diamond diggings, how they sprung into existence, before the land disputes which arose. As the country was crowded in, and elbowed each other in the necessity to get claims, the necessity for some government was felt. The first effort to establish order was made by the diggers themselves. Diggers' protection societies were formed, and committees were appointed. On the Klipdrift committee not only dealt with the differences between the diggers, but it also administered justice, and I, looking back over the difficulties of the time, and remembering how large a proportion of the community was made up of men who for a long time been wandering about the country looking for employment, and not finding any, and to say that, on the whole, justice as well as order was to be had in our English courts administered there, and order was fairly well maintained. This must be attributed to the fact that there were, on the Klipdrift side, a large number of men who had been accustomed to public life in England and in the colonies. They kept the turbulent spirits in check by punishing offences against law and order with a firm hand. The Klipdrift committee was composed of Englishmen—that is to say, of English-speaking men. They had either come from the colony from England, or they were the sons of English parents who had settled in the colony or Natal. The members of that committee had resolved amongst themselves that the men of the river should remain English. There were some Boers amongst the crowd, but they were as desirous that British rule should be maintained as were their English neighbours. This was generally the case when the intelligent Boer is not under the influence of African agitators.

The State had sent down a magistrate from Cape to administer justice in that camp. The Government had sent down a magistrate. The latter Government, with a keen spirit, appointed a gentleman to sit as a magistrate at Klipdrift, but the Klipdrift diggers understood that the Transvaal Government would not, and never would have, any control over the place. The men of Klipdrift, who led a quiet life, quietly conducted the business, and put him across saving him on the Pniel side. This was their mode of dealing with men who wanted to dig. By October, 1880, the camps were increasing with population. New rushes were being made on the river, and as soon as any new

rush was discovered, many of the diggers, who had been doing well before, left their claims and went off to the new places. Men who take to gold or diamond digging are never the sort of men to let well alone. They start on their enterprise with the idea that they are to get rich quickly, and their riches never come fast enough to hand. The *bona-fide* rushes down the river yielded, in some cases, more diamonds per individual digger than did Pniel, Klipdrift, or Hebron, and there were amongst those who operated at each place men who, from being next to penniless, soon became well off.

It was at one of these minor diggings down the river—not, however, discovered until 1872—that Mr. Spalding's diamond of 288½ carats was found. Although this diamond was 205½ carats heavier than the "Star of South Africa," it did not bring to the finder much more than half the amount of money paid by Mr. Lilienveldt for the "Star" which created the first excitement.

The men who came to sell and not to dig, seeing how eager the diggers were to get to new rushes, very soon commenced to turn that weakness to account. The schemers, who had on hand large stocks of wines and spirits sent from the colony, selected spots at some distance from the old-established diggings, and commenced digging, they themselves whispering to others that they had "found" there, and sometimes would show some fine stones which they said they had taken out at a foot or two deep. As soon as this was known, there would be a rush of diggers from the old spots to the new one, and every digger would mark out a claim for himself. Whilst this was doing, a canteen would be started, and, as men cannot dig long in a climate where it is frequently 110° in the shade, the canteen man drove a lucrative business. For some time this game answered very well. There would, as a rule, be a hundred or two diggers assembled at the new rush, all bent upon digging, and they would go on digging for a week or a fortnight before they found that the new rush was of no account, by which time the canteen keeper would have sold off all the stock he had originally of his own, and, in many cases all he could buy up in addition thereto. When the patience of the diggers was exhausted, so would his stock be; and he would then lower his tent, and go back with the diggers, deploring that the new rush had not answered. I need hardly tell you that the canteen-keeper was either the discoverer of this "rush," or an agent of his was. After a time, but not for a long time, the canteen rushes ceased to draw. Those who stuck to their claims in the first established diggings did best for themselves, as a rule, and the men who traded fairly with the steady-going digger did best in the long run.

At one time it was thought that there would be a difficulty in getting provisions and supplies, but the stock-breeder, and the butcher, and the baker, and the store-keeper, soon followed upon the grand army of diggers, and shops, supplied from the stores of the merchants in the Cape Colony and Natal, increased and multiplied as fast as the population. There never was any want of food or digging appliances at any time, although the fare was hard and coarse, and such as few of those I am now addressing would be inclined to put up

with for any amount of money. The stocks which had for several years laid heavily on the hands of the colonial merchants in the port towns, found a ready market, and the depression which, before the discovery of diamonds, had driven half the merchants in the Colonies to distress, desperation, and, in some cases, to bankruptcy, gave place to cheerfulness and enterprise, and trade in South Africa became brisk. The spirit of enterprise was quickened. The merchant increased his importations from England. The English manufacturers of picks, shovels, wheelbarrows, and corrugated iron, soon shared in the advantage of the new discovery, and the Customs returns of the Cape Colony, which had fallen very low, showed such a marked increase as they had never done before in so short a time. To give you an idea of the marked effect which the discovery of the Diamond Fields had upon trade and customs, I may remark here that the import duties which, in 1869 (the year in which diamond digging was first started), were but £1,953,091, had risen by the end of 1871 to £2,585,298; whilst at the end of 1879 they had risen to £7,080,229. With this aspect of Diamond Field history, I purpose to deal later on.

It was a remarkable feature of the Diamond Fields, in the first period of their history, that such crowds of men should have worked side by side with so little outrage. Crime of a serious kind was seldom committed. There was none of the outbreaks which in California, in the early days of digging for gold there, called the Vigilantes into existence. In that country it became necessary, for the sake of life and property, to keep a body of men with loaded revolvers in their belts—a stern necessity—and hands of ruffians were shot down without mercy. On the Australian gold-fields, bloodshedding had to be resorted to, and in the history of gold-digging in that country, occur records of brutality little less horrible than in the historical records of California.

The Californian diggings, in their earliest days, were the resort of the off-scourings of America and elsewhere. The great mass of the men who crowded the banks of the Vaal—indeed, I may say nearly all who first arrived there to dig for diamonds—were colonists, the most of whom had occupied positions in which character was indispensable. A very large proportion of the diggers of 1870, who operated on the banks of the Vaal River, were colonial born men from the frontier districts of Natal, either men who left their farms, or their businesses, or professions in the frontier towns. Those who formed these parties were most usually related to each other in some way—either by blood or business. Then a good many military men, who happened to be in the country at the time, obtained leave of absence, and joined in the rush. The first persons who came into the fields from Natal were Messrs. Glennie and King. They joined the Bethulie party, headed by Mr. Robinson, of the firm of Robinson and Marcus, of London and Kimberley, who opened up the diggings on Livingstonia (afterwards Robinson) and Hebron. Glennie had been a gold-digger in California and Australia, and he first introduced digging and cradling. Up to the end of 1870, very few persons had come from other countries to dig for diamonds.

In South Africa, as in all other parts of the

world, there are men who never work until they are compelled, and who are incorrigibly irrestrainable. There are far fewer of these in South Africa than in any other country have yet seen, but still, they are even plentiful in South Africa. They cannot long in idleness and debauchery in the town, hence they make their way to the farms, obtain a living amongst the Boers. At the towns the worst of them are found; but there are not a great many port towns in South Africa. The Diamond Fields are too far from the ports to be easily reached by such men as those I speak of. However, by about October, 1870, from the ports the farms there came, amongst the thousands, were swarming the banks of Vaal River, a hundred or two of the restless, rowdy, worthless men who never care for any settled employment. But they never had the least chance of getting the law on their hand at any of the camps. The moral force of the bulk of the diggers was sufficient to silence the idle and unruly whenever they became so. The Diamond Fields, however, had not been in existence before parties sprung up. It was curious to see how men became ambitious of power and power in that outlying region, just as it was in England, America, France, and elsewhere; it was in the contentions and conflicts of such parties that the unruly element became dangerous. They were always ready to back anyone who would or stand drinks, and would as soon about the Transvaal magistrate as an Englishman, for a price as for a diggers' protection association. It was one to them—they only cared for who paid best—who would "stand Sam" the more readily. At Hebron, the Englishman and the Dutch worked side by side without any consideration of nationality. In five cases out of ten, the Englishman did not understand one word of Afrikaans Dutch, nor the Boer a single word of English that if they did quarrel, it could not be a "blow" and a blow." Whilst, however, individuals went along together pleasantly enough without regard to nationality, there was a good deal of feeling out of the different nationalities which grew out of the several camps. For instance, the Orange River Free State, Hebron under the flag of the Transvaal Republic, and Klipdrift under no flag whatever, but the English understood to be the Klipdrift flag. The Transvaal would have liked to have taken possession of Klipdrift, and did try. The Dutch element still were equally eager with the Transvaalers to possess it, and both did attempt it. The Transvaal Government, as I mentioned before, did not appoint a magistrate, but he was put across the river. The Transvaal magistrate at Hebron put an Englishman in prison because he refused to pay a 10s. license to dig, and the Klipdrift men, that is the men on that side of the river, armed themselves, and went up and forced the magistrate to liberate his prisoner, and made his worship entertain the Klipdrift army into the bargain.

It no doubt kept the republican element in check when it became known that the subjects of Her Majesty in the Fields had memorialised. The Governor Hay, then acting as High Commissioner and Governor of the Cape Colony, to show Queen's authority on the banks of the Vaal that his Excellency had sent back a letter

power. In those days the power of England was great, wherever it dared assert itself, in South Africa, and the word of whoever represented the power was as law to men of all nationalities and races.

When I said that there was a desire amongst the Government on the Pniel side to have possession of Klipdrift, I must be understood not to mean that the President of the Free State, representing the State, had any such design. On the contrary, when I mentioned I had with him at the Presidency, in about August, 1870, he distinctly said that the Free State had no claim whatever on the land on the Klipdrift side of the river. As the Dutch Boers, I mean the majority of those who meet with in that territory, so far removed from the sea, look upon themselves as the rightful owners of all lands they can come across, which are only occupied by natives. The British Government, as I presume you are aware, did make, at the close of 1870, some attempt to protect its subjects who were operating in thousands along the banks of the river. The chief Waterboer had solicited the assistance of the Crown, years before that, to take him and his people under its protection. It has been said, and very many times, that the British Government would never decide whether the Free State or Waterboer's land in dispute between them, but for the sake of diamonds in the disputed territory. It can be further from the truth than is this, as I can prove. Years before the discovery of diamonds, Sir Philip Wodehouse, whilst High Commissioner and Governor, had taken action in consequence of the encroachment of the Boers upon Griqua territory. Waterboer had tendered his country to the Government, also years before, and his people had been anxious to be under the Government of the Free State. In 1870, when the memorial was sent to Governor Hay, then Acting High Commissioner and Governor, to take the Diamond Fields under his protection, Waterboer was quite as anxious as the memorialists that the British Government should do so. But neither the British Government nor the High Commissioner had power to hoist the British flag over new territory, and much time was lost before anything was done in the matter. At last, however, it was decided to send up a special magistrate, appointed by the High Commissioner, to administer law and justice under the authority of the Queen's chief.

I now give you an outline history of the discovery of the Diamond Fields, and of what I consider to be the present phase in their history. I shall endeavour to lay, stage by stage, until I reach the present, when art and industries have obtained a firm and secure footing there.

Regarding the arrival of the special magistrate to the Diamond Fields as the commencement of a new phase in their history. His arrival was hailed by the Boers on both sides of the river with unusual satisfaction.

It was a novel sight to see an English magistrate holding an appointment under the authority of the Crown of England and to see a chief. However, I suppose it was the

best thing that could have been done under the circumstances. Had he not arrived when he did, there can be no question that the Free State Boers would have come in and possessed themselves of all the land where the dry diggings now are, for, after the arrival of Mr. Campbell, an attempt was made to compel the diggers working at the smaller diggings down the Pniel side of the Vaal River to pay tribute to the Free State. An armed force did come into Pniel, and threatened to force diggers at Cawood's Hope, and such like places, to pay taxes to them, but the English diggers defied them, and the armed Boers seeing the attitude of the diggers thought it best not to attempt force.

I now propose to pass from the river diggings to the dry diggings. There had been, for some time before Mr. Campbell's arrival, talk about diamonds having been found at Du Toit's Pan, and Bultfontein—two farms, 24 miles from the Vaal, on the road to the Orange River Free State. The most wonderful portion of the Diamond Fields is that of the dry diggings. They derived this name from the fact that there was no water there, and the diamonds having been originally discovered in a light sandy soil, it was thought that they could be found without the diggers having to undergo the laborious operations of cradling and washing the soil before sorting, which they had been compelled to do whilst operating on the banks of the river. The first of the dry diggings to attract public attention was Du Toit's Pan, to which a few diggers had resorted before the close of 1870. Small diamonds had been found on this farm, and on the adjoining one. Du Toit's Pan belonged to a Mr. Van Wyk, and Bultfontein to a Mr. Du Plooy. It is scarcely worth while to wade through the details of purchase and sale, and the disputes and actions at law, which came out of the purchase. It will be sufficient to state that these two farms ultimately became the property of the London and South African Exploration Company, and were, when first purchased by that company, under the jurisdiction of the Free State. The work here was found to be a good deal easier than it was down the river, no water being used. The big boulders which had to be dug out to get at the diamondiferous soil at Pniel and Klipdrift did not stand in the way of working here. The ground was all soft, and of a consistency which could easily be worked with a pick and shovel. There was no breaking up of the ground after it had been dug out. All the operation necessary to get it on the sorting table, was to sift it in a sieve with a large mesh in the first place, to get rid of the large stones, and afterwards to sift it in a fine sieve, which was usually made in the shape of a hand barrow, and swung to and fro by the men holding the handles, or fastened by reins at either end to upright posts, and worked just as is a swinging cot. The process of getting through the work was very light and simple. The early diggers on the dry diggings, dug pits of about two or three or four feet deep, threw the stuff into a coarse sieve, and then placed it on a sorting table, to get rid of the large stones, then took the coarse sifted gravel, and sifted it in a very fine sieve, where the sorter, with a piece of zinc, scraped it across the table, and picked out whatever diamonds

there were to be found in it. Reports of good finds continued to appear in the columns of newspapers which were then published at Pniel and Klipdrift, and as these reports increased in frequency, so did the population in bulk. Klipdrift had long before been abandoned as diggings. It was a town of shopkeepers and tradesmen, and was fed from the down-river diggings, such as Cawood's Hope, Forlorn Hope, Union Jacket, and other diggings of that sort. Pniel was in all its glory in the early part of 1871, when there was a rush off to Du Toit's Pan. The chief part of the time of the special magistrate at Klipdrift, during the first six months he was there, was taken up with the settlement of disputes about land which existed between the Transvaal Government and the native chiefs. The Free State magistrate had become a sort of king on his side of the river, and now, when the rush was taking place from all parts of the river to Du Toit's Pan, he took care to open a second court there; and, in a very short space of time, Du Toit's Pan became an immense camp. Very large and good diamonds were found there. The proprietors of Bultfontein did all in their power to prevent that estate being rushed, but they could not withstand the will of the diggers, who jumped the place. The proprietors appealed to the Government of the Free State, but the Free State Government had no more power than the proprietors themselves to restrain large bodies of men. The best thing that could be done was done to make terms with them. Mr. Van Wyk's friends, who first worked at Du Toit's Pan, gave him one-fourth of their finds for giving them the right to work there, but when the diggers came up from the river, they were not satisfied with this arrangement, and a monthly license to dig became the settled thing. At first, the cost of the license was 7s. 6d., but was afterwards increased to 10s. By the middle of 1871, Du Toit's Pan had become a town, with hotels, stores, and shops; and then, it having been noised abroad that diamonds could be had for the picking in the South African Diamond Fields, the excitement was no longer confined to South Africa—men came from England, America, and Australia. The roads from Cape Town and Port Elizabeth to the diamond fields were full of life—vehicles of all sorts ran between the fields and the colony. A rude kind of omnibus, drawn by mules, was the first attempt made to convey passengers to and fro. For some time in 1870 and 1871 this and the post-cart were the only public vehicles by which the fields could be reached. Afterwards, transport companies sprung up, and the journey of from six to seven hundred miles was made in about eight days, and with a fair amount of comfort.

The adjoining estate to Bultfontein and Du Toit's Pan, Vooruitzicht, was the property of Mr. de Beer. He and his sons had been working Vooruitzicht as a farm, but they, seeing the success of the Du Toit's Pan and Bultfontein diggers, and that their farm partook of the same character, commenced digging at old De Beers for diamonds also. They found a few; this brought other diggers to the spot, and then they resolved to open diggings, which they did on the same terms as their neighbours at Du Toit's Pan and Bultfontein. They laid out a town and offered erven, or sites for building, at auction, on the 21st of October of that year. Nearly

up to the time when these diggings were there had been great suffering from water. One gentleman, residing at the "Pan" hotel, after being there for some time without being able to get water enough, determined to have a bath of soda, ordered the landlord to send him as many sodas as would be sufficient. This he refused to do, as he had got the soda with difficulty, in order to sell it with brandy. "Then," said the customer, who wanted to "send me the brandy with the sodas, have my sodas and b's." This the landlord refused to do. The gentleman told his friends that he had brandy and bathed in the soda water.

At old De Beers, water was found at a lesser depth than at Du Toit's Pan, and to the picturesque appearance of the place it was the most attractive, especially to the Dutch, who had brought their families with them. De Beer's afterwards became the Belgendijk Fields; it was the residence of the Lieutenant-Governor during the time the fields were real, as they should be; and, of course, the Lieutenant-Governor was, as it ought to be, the centre, around which society gathered and plumed its wings.

In July, 1871, came the crown diamond discoveries in South Africa. In the month of that July a new rush had broken out at about a mile beyond De Beers, and diamonds were found near the surface. A small "kopje," or hill, a few acres in extent, surrounded by a reef of hard rock. The place was marked out by a gentleman, Mr. F. J. W. residing in London, and all taken on a monthly license system. There was a committee of diggers, strictly adhered to, and afterwards, when the Fields had been taken over by the British, was as rigidly adhered to by them, viz., that no man should hold more than a certain number of claims; two claims were first allotted, and, afterwards, by purchase or otherwise, not sure of the number, but that it should not exceed the limit, and no matter how many a man purchased, he could not retain more than the fixed number in his own hands. Claims given out at the Colesberg thought, at about two months after the kopje was commenced, to be the thing in the world for those to whom they were given. Fine large stones were found in abundance, and within a few months after the claims had been marked out, the claims were sub-divided, and quarter claims as much as £500 and £600; whole claims, in some cases, as high as £1,000. The prudent people who saw this, and the utterly reckless men were when in search of diamonds. The De Beers were prudent men. Alfred Ebdon, of the firm of Dunell, Co., merchants, of Port Elizabeth, came to visit to the Diamond Fields, and offered De Beers £6,000 for the Vooruitzicht estate, which included the Colesberg Kopje and the diggings, and town, with a vast homestead, and other buildings besides. De Beers, at it, pocketed the money, and thought himself very fortunate indeed. Before diamonds

I have no doubt they would have taken Mr. Edden formed a company to work the trig estate as diamond fields, and the to that company were magnificent.

ever there were diggings, a town of course upround them. As it was at Pniel and Klipdrift it was at Du Toit's Pan and Vooruitzigt, to all the diggings. The last discovered were, for years, known as the Colesberg, the town surrounding them as "The New." The daily finds at this rush, immediately the diggers worked, were something marvellous, large fortunes were realised by some diggers, in July and the end of October. I just saw one illustration of the success which led on the operations, of many. A Mr. a Dutchman, bought half a claim for in two months he had taken out diamonds value of from £15,000 to £20,000.

returns as these were frequently reported, a natural consequence was that the river were abandoned for the dry diggings. Sir Henry Barkly came to South Africa as High Commissioner and Governor of the Cape Colony, as the successor of Sir Philip Wodehouse, Lieutenant-Governor Hay having filled the pointment in the interval between the of the one and the arrival of the other. I found that, whilst the Diamond Fields of the Treasury, that they needed being promptly and considerably. He, at the first possible moment, came up to see the himself, to meet Waterboer, Pretorius, representatives of all interests. He was with a heartiness he has always been acknowledge. He had been gradually the machinery for governing the Fields thing like order; but the work was not the complications were great. His Excellency to the conclusion that the Diamond could be annexed to the Cape Colony from Capetown; and whilst I, who d in the colony then some seventeen years, that such an arrangement would not was quite willing to fall in with it, for having the Fields included in the British. It must be remembered that at the time king of, the only Diamond Fields we had hand over were those on the Klipdrift e Vaal River. Pniel, and all the terri- een that and the Free State, was claimed ee State Government, and the Free State, son of a magistrate, was in possession of d all on that side of the water. I do not see what better course Sir H. Barkly e adopted than he did at that time. He ided the Cape Parliament, after his first nex the Diamond Fields, which they at is Excellency to suppose they would do. When next year came they declined. leaders of the Parliamentary majority n as far-seeing as was his Excellency, id have listened to him then.

gigs went on yielding, but confusion, want of a settled Government, grew founded. Waterboer had always con- at the land on the Pniel side, on which were situated, was his. This the Orange e had consistently disputed. As I said was not "diamonds" which originated

the dispute. The representatives of the Crown, recognising Waterboer as an ally having claims upon the British and Colonial Governments, had been desirous of putting him in possession, but the office of High Commissioner and Governor of the Cape Colony is not a light one, and the gentlemen who have so ably filled these offices during the last quarter of a century and more, had their hands too full of pressing work to be able to devote the time and attention they would like to have done to this matter of Waterboer's, or he would have been in possession on the day the diamonds were first discovered upon it. However, Sir Henry Barkly brought the matter to a point on the 23rd of October, 1871, by forwarding a document to the President of the Free State, and proclaiming, "Captain Waterboer and his people, British subjects, and the territory in which the dry diggings are situated, British territory." The proclamation made in the Diamond Fields was received with great rejoicings.

Previous to that time, a resident magistrate had been sitting at the New Rush, under British authority, and, strange to say, one had also been sitting under Free State authority at Pniel and Du Toit's Pan. The New Rush is situated between the two, in the same district, and there is but two miles distant between Du Toit's Pan and the New Rush. To get from Du Toit's Pan to Pniel, the Free State magistrate had to pass by the office of the rival functionary, the Britisher, and I know they frequently used to shake hands as they passed each other of a morning, and I have a notion that they as frequently spent a social evening together. The Orange Free State Government saw clearly that it could not control the enormous population which had now gathered round those diggings. The magistrate sent down found that the whole thing had grown beyond his control. When the proclamation was issued, and the British flag was hoisted, I am confident that President Brand and the Members of the Volksraad gave a sigh of relief—I do not mean a sigh between them, but one each, the President the biggest by far. Of course, there was a protest, sent to Sir Henry Barkly. A protest is a South African institution. Nothing is ever done to alter, or amend, or improve, or carry out anything whatever, but some one is sure to send in a protest against it. However, the protest at last brought the Orange Free State £90,000—what for I never understood yet, and I am sure that no one who reads the correspondence which passed between Sir Henry Barkly and President Brand ever will. I am sure Sir Henry Barkly does not. However, I may be allowed to say here, that I consider it worth all the money to have so good a neighbour as President Brand has proved himself to be, close to the Diamond Fields, only that I would prefer him as Lieut.-Governor of the State, to that of President of it.

The dry diggings at last attracted every one away from the Pniel diggings, and, for the most part, the diggers from the lower and minor diggings on the river. Klipdrift, as a town, held out until 1873, the residents all the time contending that the place they had settled, being the first permanent town built, was bound to be the seat of Government, no matter where the population was, or where the productive powers of the

province might be. The foundations of all the British institutions in the country were laid there—magistracies, the High or Supreme Court, and Land Commission, post-office, registry-office, and Government Surveyors' Department. Sir H. Barkly found the Cape Parliament fail him, when he endeavoured to annex the country after he had created the province and proclaimed it British territory, and he paid a second visit to the Fields about two years after.

Between the time of his first and second visit, the Government of the province had been administered by three Commissioners; but the divisions amongst the members of the Commission, and the irrepressible character of the diggers, had, before his Excellency's arrival, led to disaffection and complications; and he had seen, before leaving the Cape Colony, that some change must be made in the plan and principle of government. When he came he found the population so vast, and the magnitude of the enterprise so great, that he saw there was nothing left for him but to convert it into a Crown colony, and give the people a voice in the management of their own affairs. I can give you no better idea of the change which had taken place than to read you a sketch which I wrote at the time in a little work I myself published and dedicated to Sir H. Barkly, and which I have affixed as an appendix to this paper. (See A in appendix.)

Claims in the Du Toit's Pan diggings had been forsaken for what then appeared to be the more profitable claims in the Colesberg Kopje. At a banquet given to his Excellency at Kimberly, he said he had thought that the Fields might have been governed from Cape Town, and he had tried every means so to govern them. He found that they could not be governed from Cape Town, but must have a Legislative Council like that of Natal. He promised that he would bring this about. After this a Lieut.-Governor was appointed. Mr. Richard Southey, one of the most practical, skilful, and single-minded of all those able men who have served her Majesty in South Africa, being appointed to the office. A Legislative Council, under Letters Patent, was created, consisting of eight members—four nominated by the Crown, and four elected by the people, on a franchise that gave to nearly every one a vote, without distinction of race or colour. The Lieutenant-Governor arrived in 1873, and remained in office over three years. It will be easily imagined that it was not easy to govern so mixed a population, in which there were so many conflicting interests, and it will be as easily conceived that men, dissatisfied because they could not get all their own way, could, in conjunction with others bent on creating disturbance, soon breed disaffection. The Lieutenant-Governor was left to do the best he could, without the presence of soldiers or mounted police. An outbreak became inevitable: it took place, and a regiment of soldiers had to be sent up, under General Sir Arthur Cunningham, to show that the British authorities were not to be defied. I shall not enter into the merits of this outbreak, if merits there were. I merely state what were the facts.

During Mr. Southey's administration, the owners of Vooruitzicht, who purchased the estate for £6,000, had been taking from £20,000 to £25,000 per

annum, for rents of sites for buildings to be erected upon. The owners of it endeavoured to double the rents, and seen that it would not do to permit have such power over the town in a seat of Government was fixed, or that virtually become the Government. The Court had been removed from Barklyberley, and the whole machinery of government was centred there. I should have that, soon after Sir Henry Barkly had British rule in the Diamond Fields, the Klipdrift had been changed to Barkly expressed wish of the people there, and had been changed to Kimberley, in connection the Secretary of State for the Colonies held the same office at the time, and then had the honour to represent in the Council was named Hay, in honour of Lieut. Hay, who was the first to assist in British rule to the Fields. Vooruitzicht was chased by the local Government, with the of the Earl of Carnarvon, who was then Secretary of State for the Colonies, for £100,000, and held sites of land under a month's rental, we upon to capitalise. This was done, and way the Government found itself in a position to pay off the purchase money, and to have monthly license for Government purposes. De Beers Mine is on the Vooruitzicht estate was included in the purchase.

I must now travel back somewhat to understand how diamond mining in the West arrived at its present state of progress. What I am about to say will be understood apply more or less to all the mines, Du Toit and Bultfontein, as well as Kimberley and De Beers. It is years since those diamond could be characterised as diggings. The mines, and those who held claims in the De Beers and De Beers Mines on monthly license the owners of the claims, these having carried their claims as the standholders did then. The other mines belong to the London Exploration Company, and claims on them on monthly license holdings—the company lately given their claimholders large advance return for increased monthly payments for

Pniel and Klipdrift are no longer places people go to seek for diamonds. All that of the days of diamond digging at Pniel holes, from which men took out the diamonds, a debris of gin cases, sardine boxes, and collars. Barkly is still a town, in which there are firms (one especially, Messrs. Hill and Partners) doing a good business with the diggers on finding diamonds of first quality on the river, some 12 or 14 miles below and an interior trade is also carried on from firm mentioned.

The process of diamond-seeking has through several phases. The original claim had their claims for the marking out, and they were not called upon to invest. They found diamonds in the light, loose soil, and having, for the most part, sold when they got through that soil, sold who went on digging deeper, until it now to work low at from 300 to below the surface. When they found

hausted the soil in which they had the habit of finding diamonds, they came to a kind of loosely-packed rock, blue in colour, and to crumble. They, at first, thought they mined, that the diamonds had all been taken out, but on testing this new stratum, it was found to contain more and a better quality of diamonds than the surface soil. Then capital became necessary. The mines were gradually worked to a depth, for which the diamondiferous soil was no longer hauled out in ordinary buckets, but the top of the mine by manual labour, by means of hauling-lines. Steam machinery was employed. After arriving at a certain depth, the mines became flooded with water. The Kimberley Mine was first flooded. The water had to be pumped out, which could only be done by the use of powerful pumps worked by steam. It was discovered that there was reef in which there were no diamonds, nothing but hard rock, and had to be taken out. For this purpose steam had to be procured, and tramways made. It required a great deal of capital, and those who had no capital were compelled to give way to those who had. The general interests of the diamonders, in each diamond mine, are looked after by a Mining Board, elected for that purpose. The cost of taking out reef and water is borne by the whole body of claimholders.

There is a rough diagram, showing how the Kimberley Mine is laid out, and how it is assessed. I will explain to you.

The diagram here shown is of the Kimberley Mine, and the plan upon which that mine is laid out, applies to all the mines. The Kimberley Mine is typical in form, and its area is estimated at about seven acres. The squares you will find out show the claims, and the figures the value of each claim for rating purposes.

25 claims valued at £7,000

Assessment is far below the selling price—average 25 per cent. below. The £7,000 would fetch £10,000 in the market, the value out £8,000, and so on. This was the value of last year. In about a month there will be a new valuation, and then it will be found that the values will be much increased. The depth of the reef averages from 300 to 400 feet. This is nearly, if not altogether, worked by now, and so is the largest proportion of the other mines. For particulars, as to

shares, premiums, and capital invested, you cannot do better than consult the admirably compiled share list of Messrs. Hurly and Gray, advertised weekly in London in the *South African* newspaper.

The claims of this mine, which might have been purchased for three-quarters of a million about four years since, could not, when that valuation was made in the month of August, 1880, have been purchased for 3½ millions of money.

For some years the Du Toit's Pan and Bultfontein Mines were almost entirely abandoned, and a large proportion of the claims in both might have been held on payment of rent and water rates, and the license money. Within the last two years the high price of claims in the Kimberley Mine drove diggers to go elsewhere. Old De Beers, Du Toit's Pan, and Bultfontein were still open. A certain portion in each of these mines has always been worked from the time digging was commenced in them. Since, however, they have been worked anew, it has been discovered that they are all rich in diamonds—indeed the largest diamond that has yet been found, that of Mr. Porter Rhodes, lately exhibited to her Majesty the Queen, was found in the, I believe, Du Toit's Pan Mine.\*

The value of claims in the Du Toit's Pan and Bultfontein Mines, and, indeed, of Old De Beers too, have risen in a most extraordinary manner during the last two years. Many a claimholder has grown rich from the rise in the value of his claims alone. Since the proprietors of the Du Toit's Pan and Bultfontein Mines, and their claimholders have had their differences adjusted, the whole aspect of affairs in these two places has changed, and claims that, a few years since, were but of nominal value, are now most valuable, yielding almost as well as the Kimberley claims, and are held in very high esteem in the market.

It is estimated that there is invested in the diamond mines of Griqualand West some millions of money; and to give you an idea of the yield of diamonds, I may here mention that the value of diamonds sent through the Post-office alone in 1879 amounted to £3,685,000. The returns of last year's exportation are not yet to hand; they will certainly show a higher figure than that which I have quoted for 1879.

I have hitherto spoken only of the Diamond Fields in Griqualand West, but as the subject is the Diamond Fields of South Africa, it may reasonably be expected that I mention, however briefly, the Jagersfontein diggings. These diggings are situated near the town of Fauresmith, in the Free State. Diamonds had been found, and diggings commenced there many years ago, but the operations of that time not proving profitable, they were abandoned. About three years ago, digging was renewed there, and with at first moderate success. Latterly, however, the yield has been excellent, and the diamonds of very fine quality, and the Jagersfontein camp, in all respects, resembles those I have before mentioned at the same stage of their history. Claims, at Jagersfontein, which two years ago could have been had for a nominal figure, cannot now be obtained for less than for £900 to £1,200.

\* This I have discovered to be a mistake. It was found in the Kimberley Mine.—R. W. M.

I have as yet said nothing respecting the labour question. The working of claims, whether on the river, or in the dry diggings, involves the employment of a very large amount of manual labour, and the labour question has been one which has at times been very difficult indeed. The chief part of the pick and shovel labour is performed by natives, and when I tell you that during the last seven years 640,000 natives, who never worked for wages before, have been registered as servants to claimholders in the Diamond Fields, you will imagine how vast is the work of diamond digging in the Fields. Holding as I do that the best and surest way to civilise the natives, is to induce them to work steadily and to work for wages, I consider that the Diamond Fields have done more to civilise the native tribes fifty times over than all other efforts and institutions put together. The native earns whilst working in the diamond mines, 12s. per week in money on the average, in addition to his food, which may be calculated at 10s. per week, making his total weekly earnings 22s. The raw native, when he arrives first in the fields, has no idea how to use a spade or pick; he comes lean, naked, and stupid. That he is so, is no fault of his. Let anyone, who has watched the course of events in the Diamond Fields, speak fairly, and he will say that this native labour has been turned to good account, both for the native and his employer. You will see to-day in the Diamond Fields thousands of natives as well-dressed as the agricultural labourer of this country, and in a great many instances a very great deal better—they are better clothed and better fed. The natives here build churches and schools for themselves, and a very fair proportion of them have, after going back to their chiefs once or twice, settled down in the Fields, and have thrown off the yoke of the chiefs altogether.

Of course there are great thieves amongst them; the moral law had never been any law to them before they arrived in the Fields, and in the hands of bad men they are cunning and dangerous thieves. I do not wish you to understand from me that all the 640,000 natives who have worked for wages in the Diamond Fields have become model men—far from it. What I do maintain is that whilst they have all been taught to work, a very large proportion of them have been civilised to a very much greater extent than anyone could have calculated on, and that that civilising influence is still going on, and producing marvellous results.

I have told you in what way diamonds were first discovered in South Africa, how the diamond diggings were commenced, and how, in spite of difficulties and complications, they have been settled. Let us see, now, what the discovery has led to, and what value the Fields have been to South Africa and to this country, and of how much greater value they may still be if rightly dealt with. I should like to show, also, to the members of the Society of Arts, that Art has already advanced by their existence. We have now, in a portion of South Africa, 600 miles from the colonial sea-board, and in a part of the country that was before producing nothing, a producing power which gives about £4,000,000 per annum of raw material for the market. It has already made the fortunes of a great many people, given profitable labour to

thousands of white men, and to natives to work for wages. W large towns established round the m in which trade and commerce flouris extent, that two years since, when th were compiled, it was found that o million pounds per year was paid fo of goods to and from the ports. town has a municipality, the reven derived chiefly from a rate on house amounts to over £25,000 per annu upon the Customs dues of the Cap Natal has been, that whilst the imp Natal in 1870, were £429,527, they £2,176,356 in 1879; that the import Cape Colony has increased £5,000,0 same period. I should state here, the mining operations of the Du To having increased so much, that the South African Exploration Company, of the mine, have been compelled to for a new town. To supply the town and its mine with water, a w has been started with a capital and, I venture to say, that th this company will far exceed that water company in existence, and th and mines can afford to pay for brought from the Vaal River, a c miles, shows how great must be and the population. These Dismor employment for three banks.

is about to be laid down betwee and the two provinces of the Cape much dependent upon the trade of Fields, that they are competing with the matter of routes for the trunk which is to connect the Diamond Fi Cape Colony. Those railways wou been made but for the wealth whic Fields have yielded. The railway means of opening up the coal fields on all sides, and of which Sir Bartle to you in his lecture. It has led to England of that branch of art wh igh been exhausted—the diamond- It is useless any longer to say that only be cut in Holland. I saw yester well, at the lapidary works of Messrs Co., eighteen mills going, worked employed in cutting diamonds, and t there—all English workmen—has to be superior to that done on the would advise whoever is curious to monds are cut, or who wish to have for commercial purposes, to visit t This art of diamond cutting has est already in the Diamond Fields. Jewellers, who worked for bare wage masters there. The fields are giving in the English manufacturing district of workmen, and enriching the Brit turer. These are amongst the re wonderful discovery. I hope the t that government which Sir Henry B Provinces may not do it and the injury that I dread. The annexati land West to the Cape Colony is a bl

In the early part of my paper I reserve what I had to say on the s

questions, which have been the most disturbing of all the questions which have been raised the Diamond Fields were first discovered. It is "a Society for the encouragement of Arts, Manufactures, and Commerce," and I regard therefore this land question as one which should be put under your especial notice. I have shown how the development of the diamond mines depend upon the advancement of art and commerce, and I want you to see how great a future this store for South Africa if she is fairly opened. I have shown you some measure which has been accomplished through the opening of the Diamond Fields. I will now show what is left undone that ought to have been done. In the first place, seeing that Waterboer, and his relations before him, had been our allies, and that the Boers were as loyal to British rule as if they had been Her Majesty's subjects, we ought to have treated the Boers from over-running his country, and not to have complained to us, and we had neglected that his complaint was well founded. We neglected to do that, it was the more our fault to have taken over his territory promptly when he asked us to do so, after the Diamond Fields were open, and we saw that the Boers, both on the Free State and Transvaal side, were going to possess themselves of it. You may not know, but that it was seven whole years after we had taken over his country before we had settled the claims of those who held titles to land in the Diamond Fields made over to us, and that even Waterboer himself, who had made over the land to us, had to go into a Court of law to obtain titles to his farms. I cannot say whose fault this was, but it came of Imperial instructions. I only say that it was not the fault of the Lieutenant-Governor of the province, and although I once thought that it was attributable to Sir Henry Barkly, I am now assured that it was not the case. You may say that for some time after the special Commissioner arrived in Klipdrift, he was chiefly occupied with the settlement of land disputes. I say too that before that time the Transvaal had a magistrate at Hebron, and claimed all the land on the north side of the Vaal River. The Transvaal, however, refused to leave the borders of that territory to be settled by arbitration, Mr. Keate, the Lieutenant-Governor of Natal, being the final referee. I pray of you to give me your undivided attention whilst I explain how much depends upon the settlement of land and territory in South Africa. Sir Bartle Frere, when in the Diamond Fields, shortly before he left South Africa for England, after expressing his amazement at the wondrous progress the Fields had made, and the vast wealth evidenced on all sides of the Fields, said that if the diamonds should fail to be found—but there was no fear of that—these Fields could still prosper, for they are on the highway to the interior trade. Sir Bartle Frere was quite true. The Diamond Fields are the key to the interior trade of Africa, and if we have the interior trade, we should hold it in our hands as a precious gift not to be lightly given up. But it is useless to tell us that the Diamond Fields are on the highway to the interior trade if you permit the way between the Diamond Fields and that trade to be blocked up

against British enterprise. If other people are to have the gold and ivory, the ostrich feathers, the karosses, &c., don't tantalise British subjects in South Africa by telling them that they are on the highway to the interior trade. Let me call your attention to a rough outline map. Lieutenant-Governor Keate was called upon to decide whether this piece of country belonged to the Transvaal Boers or to the native. The two arbitrators who represented the disputants had differed, and, judging between them, Lieutenant-Governor Keate's decision was that it never was the property of the Boers, but that it was native territory. The Transvaal Government, notwithstanding this decision, persisted in keeping a Court open at Christiansburg, and the Boers continued to come into the territory and take land just when they pleased. I must say that Sir Henry Barkly took a firm stand on this matter, but he was never permitted to settle the country, although the paramount chief of the Butlapians had asked us to take over his territory and protect his people. That chief had made it clear to our Government at one time that his people would be sacrificed to Boer greed for land unless he received British protection. The promise was made to him that his country should be annexed to the British Empire, and he was comforted. That promise has not yet been kept, and we are now in imminent danger of losing much that we have gained by the grand Diamond Field enterprise, as well as that we had gained by the annexation of the Transvaal. This territory is left open for the off-scourings of native tribes to settle in, to live by plunder, and ultimately to get strong enough to make war upon the borders of either the Transvaal or Griqualand West.

Had the land of the Griqualand West territory been settled and occupied when the British flag was hoisted, the Diamond Fields would not have been altogether dependent upon the Transvaal and Free State Boer for the meat they ate, and all the cereals and vegetable stuff they required. Had that land been settled, and the Keate award put into effect, as it should have been, Colonel Warren would have had a lighter task in South Africa than he had when he was Land Commissioner of Griqualand West. Officials are reticent, but let him speak out, and I warrant you he could tell such a tale of meddle and muddle as is seldom to be found elsewhere. Colonel Warren had first to unravel the land complications of Griqualand West, and then he had to fight the natives, who had risen in rebellion because they were dissatisfied at the manner in which they had been treated in reference to that very land. Then he tried to settle the Keate award territory, but he was baffled and prevented, and it remains unsettled to this day. I am afraid to proceed further with this matter, but I desire that the members of the Society shall see how important it is for the encouragement of Arts, Manufactures, and Commerce, that the highway to the interior trade of South Africa shall be kept open from the West Coast to the East, and from East to West.

#### APPENDIX.

##### THE COLESBERG KOPIE.

Stand upon the brink of the Colesberg Kopje—that

great mine of wealth, one of the marvels of modern discoveries—and try to convey a picture of it to the mind's eye of those who have never crossed the Orange River. The task will not be an easy one; ten chances to one against your satisfying yourself that you have made others see what you see every day in the week, and are as familiar with as you are with the fingers of your own hands. But try, for all that; for there are tens of thousands of people who talk of the Colesberg Kopje every day, wonder what it is at all like, and wish they could only make out. Ask them if they have been to London. If they have, tell them to think of the London of the present day as they saw it last, or as they look upon it now, with all its palaces, theatres, churches, bridges, railways, tunnels, monuments, and statues, with St. Paul's, and its dome, and its golden cross included—aye, with all its streets, too, and its traffic, its broad and mighty Thames, rushing through the piers of the bridges that span it, and carrying ships and wherries on the face of its murky water. Tell them, when they have that picture well in their mind's eye, to imagine it all swallowed up by one sudden shock of an earthquake—sucked down into the earth as it now stands, and buried a hundred feet deep at least, and there left for ages, with all its palaces, gaudy-coloured shop fronts, its flaming column on Fish-street-hill, its river and its green parks. Think of what it would be like if, when after centuries of interment, the vast city, with all its inhabitants, had been turned into stone—one vast brown fossil, with none of the colours that now delight the eye; nothing but the forms left of everything;—that then sixteen thousand men should set to work in the centre of it all, excavating, as men have done at Nineveh, to reveal to another age the buried remnants of the past. That is to me what the Colesberg Kopje looks like. I know that there was no city buried there; but as I stand and look into the great cauldron below me, it needs no effort of fancy to trace out old cathedral doors and windows on these temples not made with hands, which are standing out in giant masses of rock from the surrounding excavations; bridges which might have spanned rivers; columns which one would think had borne the statues of heroes of a by-gone age; palaces that might have been sucked into the earth when Nature in convulsions set about making diamonds. There are, as I stand here, architectural patterns before me which it is difficult to believe are but chance lines that were made without one thinker to guide them. There is in one place as perfect a picture of the side of an old abbey, with its fantastical windows and carved doors, as if Westminster had been buried here, and had now been brought to light again. On an embankment that swarms with life, seventy feet below where I stand, are great masses of material, piled in blocks, lying in all fashions, some of them like broken rafters, halves of wheels, roofing and flooring. There are thousands of living beings climbing out of it and creeping about it. It bears a most perfect resemblance to a railway accident I once saw, and I have some difficulty in divesting my mind of the picture that had long ago passed away from my memory, and is only now again revived. A hundred fancies crowd into one's mind as one looks into and around the Kopje. It is impossible that it can be otherwise; it is so unlike anything else that one has seen, and it grows more and more wonderful every day. This time last year there were roads leading across the vast abyss, and connecting the sides and roads with each other. Carts and horses and men crossed and recrossed daily. Now the roads are gone; the stuff of which they were made has been reduced to fine sand, and men who then sometimes prayed for their daily bread, as if they knew they prayed in vain, worked for it with desperation, and for a long time almost in vain, are now living in luxury upon the proceeds of the precious stones picked out from the roadways. Not a road now intersects any portion of the Kopje; it is one

great dook, that would take the whole of the dook and breakwater, and hide it away corners. It is but fainful to picture the way; but, as far as the eye can see, it have written of it.

It needs a firm nerve to stand upon the I am now standing, and look through the the great network of ropes that cover the Kopje, as it were a spider's web spread over and, in the midst of the great buzz, to survey of the work going on. I have seen tremble and clutch the staging whilst the this great human ant-hill. I have heard I felt bewildered; and no one could wonder. The giddy heights, the noise, the bustle, are sufficient to bewilder anyone. If all the world had been driven into the Kopje, droning powers had been increased a million noise could not have been more deafening. towers of Babel had been brought with hearing, the confusion of tongues could not. There is here every type of man under He is the military man, who has dropped his the digger's cut, the navvy, the scholar, the man once about town, the young who once only rode the high horse, the yo man who never worked with anything he billiard cue before he came to this place, the divine, the lawyer, the lamp-lighter. He thrown in together, all reduced to one level alike with barrow, pickaxe, and crowbar, classifying them. For all that anyone contrary, they might all be nameless convicts number. When they heard of picking up Africa, they could never have dreamt of this, or they would never have been here.

There is not a native tribe in Africa of w not hundreds of specimens at work in this I is the stalwart Mohow, sleek of skin and some of them like giants, tearing away the and soil for their white masters; the ill-f weedy Koranna; the intelligent Zulu, and the Basuto. Of the twelve thousand at work, thousand natives, and of the ten thousand from morning till night, and all the year them, as naked as they were born. They dress most fantastically. Some are digging toiling at the wheel-barrows, which they ridges that a goat would scarcely care to work upon little ledges of rock, high up can help them. Some stand on the summit sixty feet in height, and not broader than stride. Here they work with their picks with as much unconcern as if they centre of a ten-acre field. You wonder there, and wonder still more how they are down again. Whilst you look, one of them down to fetch something, possibly a bit of his pipe with, or a drink of water, or a heat than the one he has been working with. tool, sits on the edge of the narrow platform he has been at work, puts his feet over himself round, and lies for a second or toes just over the side, feeling for You can see little dark spots that dot the mass of rock upon which this man and been working. This mass of rock was on roadway which has been removed, and it is of ten feet square, or thereabouts, standing high, with nothing to support it. It is of this that the man is coming. The bar descending has no need to fear that he sh or spoil his clothes, for he has nothing in clothes upon him but a rag of about the size fig-leaf, and an old felt hat with a feather spots you see in the sides are foot-holds which in pairs in this way:—

ving caught the two first holes, the man gradually let himself down step by step, he to grip the first two holes with his hands, came down as easily as if he had a flight ladder, with a pair of banisters on each side of him. But if the rock, which is about about brick, were to crumble away from the holes, or the edge of the platform were to sink he lays holds of it to lift himself up to it, he must be dashed to pieces, for there is no other way. But it is with the diamond-miner with the grave-digger,—

both made it in him a property of eagerness."

men get to work in these awkward and by means of ladders, some rope-ladders, ordinary builder's ladder. Never has a man an accident in going to and from his work of the holes cut in the rock, but there are accidents from climbing up rope and

One that took place a few months since to show the kind of work these men have a resident of Cape Town had been a long unsuccessful. Friends knew that he in Cape Town dependent on him for a saw that he was desponding, and at last he made a claim to work on the mine. He went

It was a very deep claim indeed, and he reached by going down a ladder made of rope, from the top to a ledge fifty feet deep. From that ledge there were ladders sent from ledge to ledge, until the bottom. He had gone down safely, looked at the taken samples of it, and came up all right upon which the rope-ladder rested, and feeling his nerves fail, lit his pipe few whiffs. He then proceeded to mount, as within fifteen feet of the top he felt his legs give way. He thought he could not go up, so he slid down again to the ledge, for a little while, and then made a claim. When within ten feet he became giddy. He was fixed to a chain, which he had to hold over his head, he felt he could climb no more, utterly failed him, and he slid down the rope-ladder all right, but when he got out ten feet of the ledge the rope-ladder broke, and he fell with the piece of rope in his hand, was fearfully smashed, but he lived to

and frightful falls without being much more than hurt, and came up unhurt. A man, aggravated by another, on his claim, between forty and fifty feet fell came up again as lively as before, not even scratched. The greatest fear apprehended is from the falling in of the pieces have fallen in, and men have been killed. It has been predicted that the mine will fall in; and if that were to take place the lives must be sacrificed. There have been many deaths since then, and many lives have been lost of white and coloured men.

## DISCUSSION.

Mr. James Fries, in offering some remarks on the able paper which had been read to the meeting, would not attempt to criticise it, recognising as he did the amount of information contained in it. Mr. Murray had brought before the meeting details of the history of the South African Gold and Diamond Fields, which had not previously been made public, but which he had been able to give from his personal knowledge and experience. No doubt the Diamond Fields would have a very great effect upon the future of South Africa, and their existence would facilitate the creation of roads in the country, and would assist in opening up the interior to commerce. New fields were greatly required for our manufactures. One very important matter in connexion with the Diamond Fields was the employment of native labour. The natives were now taught to work, and native labour would in future be an important element in opening up the territory. They were now taught to wear clothes, which were sent as manufactured goods from this country; and, as the habits of labour and the requirement of clothing became more recognised, wider fields of commerce and for the consumption of English manufactured goods would be opened. Of the immense value of the Diamond Fields no doubt could be felt, seeing that the proceeds sent to this country amounted to £4,000,000. Probably many of those engaged in cutting the diamonds sent from Africa were present, and to them the paper would be specially interesting, as there had now been restored to this country a trade of which the Dutch had hitherto had almost the exclusive monopoly, and it was to be hoped it would become more and more developed.

Mr. Froudes questioned the pertinence of some allusions to Australia, which occurred in one or two paragraphs of the paper. He had been a resident in Australia for many years, and could testify, from his own experience, to the general high character of the Australian colonists.

Mr. Charles Fraser thought the paper presented as perfect a photograph of the parts of South Africa with which it dealt that it could hardly give rise to any discussion. It would be especially valuable to the industrial section of the community, as showing them what an excellent field for their labour South Africa presented. That remark would certainly apply to almost every colony in her Majesty's empire, and if the paper should be the means of inducing the agricultural population of this country to emigrate, it would be a benefit generally to the empire. Out of about 16,000,000 people in this country who laboured with their hands, at least 50 per cent. were idle for two months in the year, and assuming, for the sake of argument, that they earned about £3 a week all the year round, by the dearth of employment each man lost about £16 in the year, which sum, multiplied by 16,000,000, showed not only the aggregate loss to the working classes, but a loss of purchasing power which affected the entire manufacturing interests of the country. He would therefore say to the working classes of this country, "emigrate by all means." He, too, was an old colonist; and Mr. Murray would recognise in him one who stood beside him when the Diamond Fields were looked upon as a myth, and when the leading merchants in South Africa would not even advance £10 towards exploring them, so doubtful were they of any return to be obtained from them. If the paper should have the result of inducing working men to go out to that country, it would have achieved a worthy object, and one which he believed Mr. Murray had very much at heart.

The Chairman entirely agreed that the paper showed a high degree of thoughtfulness, and that it could not but be attended with a good result. Mr. Murray had told, in the plainest and clearest way, the history of that wonderful province, which though one of the smallest and most

recent, was certainly one of the most remarkable among the dependencies of the British Crown. Scarcely anything in books of imagination, or even in the "Arabian Nights," was more wonderful than the story that had been narrated in the paper. That a tract of veritable wilderness should become more valuable and wealthy than the most valuable centres of the wealthiest capitals in the civilised world, was a fact that seemed hardly credible, but these Diamond Fields, in a remote desert, had, in truth, become more valuable than any land in the centres of civilisation. Another interesting fact disclosed by the reader of the paper was the connection established between the highest civilisation and the depths of barbarism, for they found that, by an extraordinary chain of circumstances, high art, science, and even luxury, were contributing in a remarkable way to elevate the natives, and to ameliorate their condition. Those who, in the great cities of Europe, India, and America, spend their surplus wealth in the purchase of diamonds, contributed, perhaps little knowing it, to the improvement, in a wonderful degree, of the natives of South Africa. Missionaries, good men as they were known to be, must, after all, teach the native that his condition can only be improved by labour. The civilising influences in all countries were really the spade and plough, and colonists who taught the natives to labour, were as true pioneers of civilisation as any other class of men. In that respect, therefore, the colonists of Griqualand West, who were employing native diggers were rendering yeomen's service to the cause of civilisation. A very fair remark, he considered, had been made by the gentleman who spoke on behalf of the Australian colonies, but he did not suppose for one moment that Mr. Murray intended to throw any shadow of reproach upon them. It was of the highest possible consequence that the colonists of every colony of the empire should endeavour to work amicably and conjointly together, because after all, the empire depended to a great extent upon its colonies, and the day was not far distant when those colonies must be brought into closer contact with each other, and with the mother country. That result could only be brought about at an earlier date, as contrasted with some distant period, by their striving together in a common work. It only remained to propose a hearty vote of thanks to the author for his paper.

The resolution was carried unanimously.

Mr. Murray, in acknowledging the vote of thanks, said that he had no more intention of reflecting upon Australia than upon California, or upon South Africa itself. All he wished to point out was the comparative amount of crime in the colonies, not committed by the colonists themselves, but, as in the case of California, by the waifs and outcasts which had drifted there from all parts of America. As he had told them, though there were but few ports in South Africa, they received some outcasts from society as well as America. He had certainly no intention of reflecting upon Australia, which he himself held to be one of the gems and great glories of the empire. He was greatly obliged to the meeting for the attention they had given to his paper, which showed that they realised the importance of the subject brought before them. Whatever the character of the seed he had attempted to sow might be, it had been sown in good soil, and he was especially glad that so many of the industrial classes were present, for it was his great desire to assist labour as far as lay in his power. He felt that he had far from exhausted the subject or done it as much justice as it deserved, but he had done his best to present a plain narrative of the history of the South African Diamond Fields in the time allotted to him, without wearying the audience with dry details and statistics. At some future time he hoped to be able to fill up the gaps left in the paper.

#### FIFTEENTH ORDINARY MEET

Wednesday, March 16th, 1881; L. S. CHURCHILL in the chair.

The following candidates were proposed for election as members of the Society:—

Adlam, James, 28, Aldebert-ter., Clapham  
Beaumont, Colonel F., R.E., 3, Victoria-minster.  
Browne, Harold C. Gere, M.A., 6, Lincoln's-inn, W.C.  
D'Avigdor, E. Henry, B.A., Derwent Acton, W., and 15, Great George-street  
Donaldson, J. Hunter, 176, Oxford-street  
Greenbough, David William, 9, Mincing-Henry, Ebenezer Walker, 27, Belaise-orestead, N.W.  
Maberley, Capt. Thomas Astley, 25, Park S.W.  
Mansfield, George, 104, New Bond-street  
Potts, Benjamin L. F., A.M.I.C.E., 174, grove, S.E.  
Price, John Edward, F.S.A., 60, Albion Newington, N.  
Welsh, Thomas Deball, 79, Arthur-road, 1

The following candidates were balloted for as duly elected members of the Society:—

Appleby, Herbert, Durness, Littleborough  
Attwood, George, F.G.S., F.C.S., 7, Regent's-park, N.W.  
Hall, W. H., Weybridge-leath, Surrey.  
Rattray, Netlam, 70, Gloucester-terrace, E  
Richardson, Captain John Frederick, Houghton-house, Stoneygate, Leicester

The paper read was—

#### THE BEAUMONT COMPRESSED MOTIVE FOR TRAMWAYS, RAIL

By Colonel F. Beaumont, R.I.

From the earliest ages, the imports tating locomotion has been recognised as a civilising effect of interchange, whether material, has been increasingly as greater facilities have become available introduction of wheeled vehicles, the step forward was by macadamising on enabling coaches to be run at speeds attainable. Three days was the ti London and the "Old Black Swan" testified by the placard over the steam superseded coaches, the latter to fourteen miles an hour. Rails before the introduction of steam up the full value of reducing the rolling carriages to a minimum was never appreciated by the public till steam rendered a possibility, and consequently car tracks to be an absolute necessity. T tion of the iron rail became general found that not only would the cost reduced, but concurrently a speed possible quite unattainable with horse.

After railways, tramways form the step in the progress of locomotion. the difference between a tramway as to be that the former is used for while thus enabling cheaper work to be the tram-car shares the road with of whereas the latter carries a high spe

ively its own. The conditions under which the systems have to be worked are dissimilar, and its relative advantages and disadvantages may be put down as follows:—

The railway commands all the movements on its line, and can so choose its own rate of speed, limited only by considerations of safety. It has, the most expensive in first cost, certainly the best perfect means of reducing to a minimum its working expenses of carrying a large quantity of traffic, while it enjoys the monopoly of high speeds. On the other hand, its cost is enormous, and the standing charges necessarily heavy. Its system is inelastic, and until a railway has actually made traffic for itself it cannot pay. It is usually computed that it takes seven years for an average line to create a remunerative business—or, in other words, a travelling public around it—sufficient to make it fairly to rank as a paying concern.

In the case of a tramway—assuming the rolling resistance to be something not very far from a railway, and that a means is found of applying mechanical in place of animal power—how will it compare stand? It is cheap to construct, and it has no land to pay for. It must accommodate its traffic to that of the road, and, consequently, can only move slowly. It is able, however, to adjust its working expenses, to a certain extent, to the work it has to do; and it taps traffic and routes which a railway cannot touch. On the other hand, it labours under the great disadvantage of gradients, and the obligation to divide its line into small portions, thereby necessitating the smallest, and consequently the most expensive, of engine. Notwithstanding these circumstances, it appears to me that the tramway system is about to become a formidable competitor to railway for a certain class of traffic, provided horse-power can be superseded by mechanical power. A consideration will show that a tram engine works under conditions enormously less onerous than those of an ordinary locomotive. Let us take the case of a fast train running out of London—say, on one of our main lines. An engine drawing such a train would need to do the work of 1,000 horses, and for its journey, so far as gradients are concerned, it will not be required to vary its power more than to a moderate extent. The engine will cost £3,000, which must be set against the cost of 1,000 horses at £40 each—say £40,000. Of course these figures are only used for the purpose of comparison, and do not refer to the number of horses required to continue doing the same amount of work. Now a tram-car is actually drawn by two horses, value £80 (about 10 horses per car are required for continuous working), for which it is proposed to substitute an engine at a cost of £700. Moreover, owing to gradients, the tram will require to vary its force very largely, and power has to be provided corresponding to the maximum inclination, however small a portion, the incline may bear to the rest of the road. A tram engine is, therefore, in a worse position than a railway locomotive in working economy as against horses, and this active of other important considerations, is unusual wear and tear from its machinery close to a muddy road, or the shaking due to its running on an uneven track.

The great difference between a steam-engine for tramway and ordinary locomotive purposes, arises from the necessity which is thrown upon the tramway engineer to fulfil certain requirements which are not needed in the case of a locomotive. They will be readily understood from a perusal of the requirement of the Board of Trade, as laid down in the report of the House of Commons Committee on the application of mechanical power to tramways. The difficulties arise from the small space available, and the absolute necessity of avoiding the emission of smoke or steam, the machinery, too, requires to be completely covered; and certain mechanical controls are asked for on the tram engines, which are never used on ordinary locomotives.

The difficulty in these connections will be recognised, when it is considered that a detached tramway engine weighs, say, seven tons, and stands on a small wheel base. Within this, a powerful engine and boiler has to be arranged, with the pumps, injectors, brakes, arrangements for condensing, and other details. To this is added an automatic brake, with regulator and speed indicator. The driver, therefore, has no inconsiderable number of handles within his reach, the manipulation of which he is responsible for. Moreover, these must be so arranged that they can be worked from either end of the engine. Any arrangement for condensing the steam, involves weight and complication, while the smoke can only be killed by a proper choice of fuel.

With reference to the second point, unfortunately, though smoke may be avoided by a proper choice of fuel, it is quite impossible to stop noxious fumes.

I make the above remarks, as it was from a consideration of the requirements necessary to meet the case, and an appreciation of the great difficulties in the way of steam, that I turned my attention to air. The reasons are obvious which recommend compressed air as a motive power. It is noiseless; it is smokeless; it is cleanly; it offends neither the ear, the eye, or the nose. A service of air-cars would be run in the following manner:—At intervals of every 10 miles compressing stations would be established, where the air would be compressed to the requisite amount by steam, or water power where available. These stations need not necessarily be on the tram line, as no loss worth noticing would be incurred by carrying the compressed air any reasonable distance, provided pipes of a suitable size were used. The charging would be done from a connection to be made between the engine and a tap, in a suitable box placed between the tramway lines beneath the road, of no more inconvenience to the public than a water hydrant.

There is nothing new in the proposal to apply compressed air to locomotive purposes, and when the advantages are so obvious, it is not remarkable that many efforts have been made to overcome the one weak point, viz., the difficulty of arranging so that a sufficient amount of power is available for practical purposes from the storage of a reasonable bulk of air.

The earlier efforts were confined to simply compressing air at a comparatively low pressure, say 200 lbs. on the inch, in a suitable receptacle, and allowing it to expand into the working cylinders of an ordinary air-engine. It is impossible thus to get a satisfactory result, as a glance at the tables on

THE BRAUMONT COMPRESSED AIR ENGINE.

EXPERIMENTAL ENGINE.

SECTION OF METROPOLITAN RAILWAY RUN OVER BY THE BEAUMONT AIR ENGINE.

the wall will show the small quantity of power contained in a cubic foot of air at 200 lbs. Further, if no means are taken to supply heat, there will be a very serious loss of power from the cooling of the air during expansion, as will be explained further on; and, besides, the engine would soon be stopped, from the ice which would form in the ports of the cylinders, and block them.

More recently, far better results have been obtained, getting over the latter difficulty, by mixing steam with the air. This formed the subject of a very early patent, now expired. The machines, however, still use low pressure air in the cylinders, some form of reducing valve being employed to reduce the high reservoir pressure to the low pressure at which the air is admitted to the ordinary working cylinders of the engines.

These two specialities, viz., the mixing of air and steam together, and the use of a reducing valve, are both absent in my engine, which I will now briefly describe.

The engine is constructed so as to admit the full reservoir pressure, no matter how high it may be, direct to the working cylinders of the engine, without any wire-drawing, or, in other words, loss of pressure whatever; and arrangements are made by which the heat necessary to prevent the formation of ice, and to keep the temperature from falling during expansion, is supplied by externally steam-jacketing the cylinders.

A small generator is carried in a convenient corner within the framework of the engine, which supplies a sufficient amount of steam for the above purpose. The steam, which is condensed by the expanding air, runs back into the boiler; hence no pump is needed, and the grate area is so small as to be of absolutely no inconvenience; the whole apparatus is completely out of sight.

The engine is provided with variable expansion gear, which works distinct from the positive action given to the valves by the eccentrics. The expansion arrangement works so efficiently, that the air can be entirely shut off by its use; indeed, the driver controls the engine by the expansion, and not by the throttle valve.

The pressure I am working at is 1,000 lbs. on the square inch, and the sizes of the cylinders are so arranged that, even when the engine is working considerably above its normal power, there is cylinder capacity sufficient to allow the air to be reduced to the atmospheric line before it is discharged, thus ensuring the whole of the energy which is stored up in it being made available. The power of the engine remains practically constant till the whole of the air in the reservoir is exhausted down to the working pressure, thus rendering unnecessary any special reserve of air for mounting inclines. This is effected in the following way:—The power developed at any given reservoir pressure is in direct proportion to the quantity of air consumed; the use of the expansion valve, together with the power of admitting a sufficient amount of pressure direct from the reservoir into the big cylinders, enables the quantity of air consumed to be varied in proportion to the work required to be done.

There is, of course, no particular virtue in the pressure of 1,000 lbs., and it was arrived at by me in the following manner:—I found from inquiry amongst tramway authorities that, though there

were many short lines, any system of mechanical traction, to ensure its general adoption, should be capable of running ten miles without refilling. To be on the safe side, I take the resistance to motion on a fair and level tramway at 25 lbs. per ton assuming a gross load to be drawn of 12 tons engine, 7 tons, and car 5 tons. This will run

$$12 \times 25 \times 50,000 = \text{say } 500 \text{ h.p., to be made}$$

33,000

to go a distance of 10 miles.

Assuming that one-third of the total stored up in the air could be rendered available, it will be seen that, with a reservoir capacity of 100 cubic feet, it is necessary to maintain at 1,000 lbs. pressure, to be master of the required amount of work,  $\frac{100 \times 15}{3} = 500$

If 500 lbs. pressure is used, at least 200 cu. ft. of reservoir must be provided, and in either case much larger amount will be needed, if a further loss has to be incurred by wire-drawing from the higher to the lower pressure.

The engine stops and starts with the same ease as an ordinary locomotive; the use of the high pressure enables, in the high pressure ports of the engine, very small cylinders and valves, slight travels to be used; hence I consider the machine will be found peculiarly economical of repairs. The cylinders and valves of the engine already made have never required to be touched, and there has hitherto—after extended trials—no sign at all of wear. The joints require making to stand 1,000 lbs. pressure, but once they can be relied upon. With any system storing power by compressed air, it is also essential, not that leakages should be reduced to a minimum, but that there should be actually none. By the courtesy of the Arsenal authorities, I was able to satisfy myself that this condition could be relied upon. In the laboratory department Davidson is daily using air at from 1,000 to 1,500 lbs. pressure, and he has assured me that the use of compressed air gave him no more trouble than steam, as the arrangements necessary to be made were not so complicated.

I will now summarise the results which have been obtained in actual practice with my engine, and then offer a few remarks on the conditions involved in the use of compressed air.

The No. 1 engine, made by Messrs. Messrs. Wardle, and Co., of Leeds, was run for the first four months in the grounds of the Royal Arsenal, Woolwich, where in course of continual work it drew a gross load of 23 tons—11 miles, and 11—21 miles respectively, with one single charge of 100 cubic feet of air. It subsequently made a trip of some 16 miles on the South Eastern Railway, from Dartford to Woolwich and back, and then ran on the Metropolitan (Underground) Railway, and a section of the line passed over which was kindly furnished to me by Mr. Tomlinson, and appended to this paper. The engine and car together weighed about 20 tons, and over the line with some fairly heavy curves and gradients the duty done was three tons conveyed one mile, expenditure of one cubic foot of air, at 1,000 lbs. initial pressure.

The same engine, weighing ten tons, had a 42-ton Metropolitan engine, with its steam engine, and on a very bad road, this showing the

At the works of Messrs. Adamson and Co., who we made the reservoirs I am now using; the engine was lifted off the ground and put under a dynamometer, and an actual result was obtained on 6 h.p. (for one minute), for each cubic foot of air expended, from 1,000 lbs. This is about 33 per cent. of the h.p. expended in the work of compression.

A No. 2 engine, specially made for tramway purposes, with a reservoir capacity of 60 cubic ft., will very shortly be at work, under a contract with the North Metropolitan Tramway Company, to work their Stratford, Leytonstone, and Haringey Forest line. It has been tried most successfully on the Leeds tramways, and also for shunting purposes at the Victoria Docks. I append a statement by Mr. Carr, the engineer to the Docks, of the work done. It will be noticed that the result shows one ton moved one mile, for the expenditure of one cubic foot of air:—

"January 27.—Air-compressed locomotive made for railway rail, weight about 7 tons, working on a piece of straight level line in the Royal Albert Dock, back of the shed, 100 yards in length, drawing an open truck weighing 5 tons laden with 1½ tons of brick rubbish. Weight moved, including engine, 23½ tons (engine 18, truck 5, bricks 1½ = 23½ tons). The engine was used at every journey of 100 yards. The pressure at starting was 925 lbs.

Pressure.	Minutes.	Lbs.
5 lbs. ran 1,000 yards in 9, reduced pressure to 865		730
5 " " " 9, " " " " " " " "		600
5 " " " 13, " " " " " " " "		505
5 " " " 10, " " " " " " " "		520
yards run. Loss 405 lbs. in 50 min. 3 miles 73 yards per hour.		

Pressure.	Minutes.	Lbs.

" " " 10, " " " " " " " "		205

4,000 yards run. Loss 315 lbs.

gross load of 23½ tons was taken a distance of ½ miles, with a diminution of 720 lbs. from an pressure of 925 lbs. per square inch, in a reservoir of capacity of 60 cubic feet. This is equivalent expenditure of 42 ft. of air at 1,000 initial pressure which represents for the work above mentioned a (say) 3 tons conveyed one mile for each cubic foot of air consumed. The line was straight and level, on the other hand, 90 stops and starts had to be made in the distance run.—ROBERT CARR."

As results have been got with engines that are, as a little stiff, owing to their not being yet in work. From this cause, and by using certain arrangements for getting more heat into the engine during expansion, I anticipate obtaining results than the above. Taking, however, as they stand, they mean that the expenditure of from ¾ to 1 lb. of coal will take 3 tons on an ordinarily level railway, or develop 1 horse power under a dynamometer.

compressing engines now erected at Stratford indicated at Messrs. Adamson's Works, was from the results there obtained that the estimate is made of the coal required to produce one cubic foot of compressed air.

use of compressed air, as ordinarily understood, means only the reproduction of the power used in the act of compression, whether steam or be the agent employed. This, however, is strictly true with reference to the latest form

of engine, as heat is supplied to the air during expansion, thereby supplementing the store of energy received from the original source.

As mentioned earlier, the whole difficulty in connection with the use of compressed air arose from the loss of power involved in the way in which it has been hitherto used. The rationale of this is as follows:—Heat and power are exact mechanical equivalents, as shown by our talented countryman, Dr. Joule; or, to put it more plainly, any expenditure of power produces heat, a corresponding amount of cold being developed in the source of energy. This being so, the air, as it is compressed, receives the heat due to the mechanical energy employed in compressing it; and, in accordance with a well-known law, the pressure increases in proportion; as it is impracticable to keep the temperature of the reservoirs above that of the atmosphere, it is lost. When the air, in its turn, becomes the working fluid, the energy developed requires heat, which must be obtained (if no external source is available) from the air itself, the cold produced, or rather the heat abstracted, being in exact proportion to the power given off. It will be seen from this that, if arrangements are made to withdraw the heat of compression, and supply an equal amount during expansion, the power given off by the working engine will correspond with that absorbed by the compressors, the expansion and compression curves being on isothermal lines. It is to supply this heat that the cylinders of the engine are jacketed with steam; each unit of heat abstracted from the steam prevents a corresponding drop of temperature, and, consequently, of pressure in the working cylinder; in other words, it is turned into mechanical energy. At the commencement of my experiments, the doubtful point was whether a sufficient amount of heat could be got through the walls of the cylinders to materially affect the temperature of the air within. That my system effects this is shown by the air being exhausted at about 100° Fahr., when the engine is doing a normal amount of work, and by the reduction of steam pressure in the small generator, which takes place directly the locomotive is started, showing that the energy produced in the cylinders absorbs heat, which is abstracted through the metal of the cylinders from the steam surrounding them, a corresponding amount of which is condensed, and trickles back as warm water to the generator to be reevaporated.

I have not yet had an opportunity of indicating the cylinders either for temperature or pressure, owing to the high pressure used necessitating special appliances, but I hope shortly to be able to do so, when a proper curve of expansion could be laid down. It will be noticed that any admixture of air and steam must be a source of loss if the same temperature could be got without it by external jacketing, as, in the former case, hot water would be discharged into the atmosphere. For the purpose of proving the correctness of my views, I introduced, as an experiment, steam into the second cylinder of my No. 1 engine. The pipe supplying it was furnished with a back valve, so that, while the air could not enter the steam pipe, the steam could mix freely with the expanding air, so soon as the pressure of the latter was below that of the former. Just as much steam was admitted as could be done without its showing at the exhaust. Comparative trials were made with the same engine, worked

under the two circumstances, at the works of Messrs. Manning, Wardle, and Co. (the makers of the engine, at Leeds), and it was found that no gain in effect was produced by mixing, whereas the convenience of the original arrangement was obvious; it was therefore finally adopted. The temperature thereby obtained is amply sufficient to keep the lubricating medium employed in a proper condition, and there is absolutely no difficulty at all in practice from this cause.

The Table below shows very clearly the importance of avoiding the loss which a reducing-valve entails, viz., a direct loss of no less than two-thirds of the whole energy stored up, if the air at 1,000 lbs. pressure is allowed to expand to ten times its bulk, i.e., to 100 lbs. on the inch, before it is admitted to the working cylinder. This large loss would be still further increased in practice, as the average pressure at which the air would act on the piston would be considerably lessened by the throttle-valve. Where the value of the system depends altogether upon the amount of available energy which it is possible to store up, it is of the first importance to lose none of it.

TABLE.—SHOWING AMOUNT OF POWER STORED, AND LOSS FROM THE USE OF A REDUCING VALVE.

Pressure above the Atmosphere in lbs. per square inch.	Ratio of Expansion.	Hyp. Log.	Mean Pressure during the stroke.	Mean Power in 1 Cubic Foot of Air.	Horse Power in 1 Cubic Foot of Air at 1,000 lbs., when wire-drawn to	Percentage of Loss from Wire-drawing from 1,000 lbs.

200	41	3,713,571	40.70	7.38	12	16.0
100	34.33	3,536,017	35.04	5.69	11.31	23.8
400	37.66	3,319,984	34.79	4.19	10.34	28.1
300	31	3,044,519	30.88	3.80	9.02	36.7
200	14.23	2,692,352	24.94	1.43	8.27	51.3
100	7.66	2,005,049	15.55	0.58	4.58	68.1

It appeared to me absolutely essential, before compressed air could come into practical use, that some construction of engine should be designed which would avoid the great loss which wire-drawing from high pressures would entail. The modern practical steam engineers recognise the desirability of this; and if it is necessary where steam is used, it is infinitely more so in the case of air where the fluid is more costly, and the loss from wire-drawing greater in proportion to the increased difference between the reservoir and boiler pressures respectively, and those in the cylinders.

The curve shown in the diagram expresses graphically the available power at different pressures and the loss from wire-drawing. The difference between an engine working with or without complete expansion may be conveniently likened to the work done by a man on a treadmill, in the one case stepping directly on to the wheel from a high platform, and in the other, having mounted the platform, walking two-thirds of the way down again before putting his weight on the wheel.

I have before alluded to the new system has given, and the highest is fairly be claimed for them in special for the working of underground railways, and to supersede the employ in mines. The entire average of English tramways is, approximately mile run, while the receipts are 16 pence, 4d., representing the interest dividend on the capital employed.

The Company now working is willing to undertake the tracting 1 6d. per tram mile, which corresponds about 1d. per mile over horse traction for two-horse cars, 7d. per tram mile will increase tramway dividends 25 per cent of releasing the capital rep horses now employed, which is Moreover, a change from horse traction is desirable, from a human view; the strain put on the tramway severe, owing to the weight to be an inelastic character of the load, and on inclined lines the condition often pitiable.

In mining, too, the horses and men have by no means happy lives, and with a heavy train of tubs behind step may cause them to fall in front while the lights they are supposed to be constantly wanting; as they are so much too, the tender mercies of their directors public control. Any system of would be an unmitigated blessing of the brute creation which is underground.

The Channel tunnel scheme, now have actually commenced, is at public attention, and it is hardly statement to make, without air tunnel could neither be constructed able time, nor properly worked without.

The most difficult problem in its construction is how to remove the small opening the debris, and into and material necessary for the work, the working faces being peril the entrance.

No system of traction by horses and its speed would be confined to three Ropes would be impossible, as the trains would be continually vary No amount of artificial ventilation steam locomotives to be used. The however, not only overcomes all that but it actually improves the ventilating the permanent traffic, taking the of the train to be 200 tons, this is cubic feet of air per train mile, or do the 20 miles between the French coasts. A 60-ton engine could easily; there would, however, be difficulty in having an air machine charged, extending the length of which, in the event of the necessary engine could obtain the supply of.

As regards the Underground Railway recently made show the perfect working the traffic by compressed air, resolving itself entirely into one of

ing expenses cannot vary much one way  
the if air be substituted for steam, no  
heavy first outlay would have to be in-  
plant. The public papers team with  
stems and articles on the injurious effects  
to the bad gases and defective ventila-  
tion. It rests with the public to judge  
they will be willing, should it be neces-  
sary, to pay a little more for their tickets and  
luxury of fresh air. My own impression  
about the railway would be more than  
offset by the gain, but at the very out-  
line (if less it were) would be covered by  
savings in the fares. The science of  
power on a large scale is only in its infancy ;  
new field is opened, if only it is found  
that, to manufacture energy at fixed centres,  
by the power of locomotion ready for use.  
I doubt that compressed air has a very  
long before it, and those who are first in the  
field are the first to reap the benefits arising  
from it.

## DISCUSSION

times and they must feel indebted to Colonel  
for this new invention of his, which assumed  
in the future to occupy a very prominent  
It was no longer an hypothetical scheme,  
a practically tried at Woolwich, on the  
sea Railway, and on the Metropolitan  
a actual work, and it had since been  
: tramway which was about to adopt it.  
to him that the main principle consisted  
not in combination with the pressure of  
e they knew, simple compressed air had  
ofore, but had never succeeded in any prac-  
Colonel Beaumont, however, appeared to  
the difficulty by jacking the cylinders,  
and he obtained greater elasticity in the  
rest saving in the use of it. This seemed  
but all great inventions were simple. He  
enter into the mechanical construction of  
which was not immediately before them,  
singes appeared to be very great, especially  
f tramways. He did not think tramway  
to compete injuriously with railways, but  
to be made very valuable as auxiliaries and  
and; and this invention was specially cal-  
culated that movement. In the country you often  
station which was two or three miles from the  
anted to go to, and if the railway companies  
note tramways in such situations where it  
may to make a regular railway, the amount  
which would be developed would be very  
high.

There were many difficulties con-  
cerning the use of horse-power; horses re-  
quiring, grooming, and stables; they got ill,  
and died; whereas an air-engine was free  
from drawbacks. Once provided, all you had  
to fill it with air by means of a steam-engine,  
an engine of enormous power entirely under  
which you could convey a considerable load  
several miles with ease. The only question was  
the engine for compressing the air, which  
could, no doubt, in some cases, be effected  
by wind or water power.

he remarked that all who travelled by the  
Railway would be grateful for the  
of the evils of smoke, noise, and heat  
which they had to endure on that most  
convenient mode of transport. It was one of the elements given  
to the world by human ingenuity to  
overcome it. Colonel Beaumont had

practically shown how it might be used, and no doubt many ingenious men would soon be turning their attention to the improvement of this apparently simple but most useful apparatus. He would suggest that the heat required around the cylinder might be obtained by the use of liquid fuel—a subject which had been for some years before the Institute of Naval Architects, and thus the necessity for having a stoker would be avoided. This saving effected on the Underground Railway might go a good way towards the cost of providing the stationary engines for compressing the air.

Mr. S. Stevenson said that two of the Mokariki detached air-engines were placed on the Wantage tramway in July last, and continued to work the passenger traffic of the line between the town and the Great Western Railway Station at Wantage-road until the following October, the pumping station for supplying the engines with compressed air having previously been set upon a piece of ground in the tramway station-yard at the Wantage end of the line. The engines ran on ordinary days four journeys, each to and from the town to the station, and on market days and special occasions five journeys each, often taking two loaded cars up and down. No goods traffic was conveyed by them, but a trial was made on a portion of the line with a heavy truck-load of coals, which one of them moved with ease up a gradient of 1 in 44. The distance travelled over by each engine without a fresh charge of air was, as nearly as possible, five miles, and the quantity of air required for propulsion varied according to circumstances, but generally exhausted about 70 per cent. of the quantity stored in the engine and car for the service. The apparatus connected with each engine for carrying the supply of air for the journey consisted of four strong steel cylindrical vessels, three of which formed the battery, and one the reserve. The air at starting was compressed into them containers up to 30 atmospheres, or 660 lbs. to the inch. After the journey, the pressure generally ran down to about 5 atmospheres in the battery, and 27 atmospheres in the reserve. The air, before passing into the cylinders, was expanded by being forced through hot water at a temperature of about 300° Fahr., which gave it additional moisture, and acted as a lubricant to the cylinders; the pressure at which the air was supplied to the cylinders varied according to the propelling power required, but seldom exceeded 70 lbs. to the inch. The speed at which the engines travelled on the line averaged about nine miles an hour, but from the pressure available, it was clear almost any reasonable speed could be easily attained by them. The smoothness and freedom from clatter, hissing, and noise of every description, was very great, and on no occasion did he observe the slightest appearance of vapour, steam or smoke, either from the cylinders or the exhaust, and he was not aware of any horse having been frightened the whole time the engines were running. He was not able to ascertain the cost of producing the air for the propulsion of the cars per mile by the Mokariki air-engines, as the air-engine company worked the traffic for three months at their own expense, but as far as he could learn, it took about 24 cwt. of coals per day to produce the power necessary for propelling the cars. He did not consider, in this respect, that anything like the best results of compressing the air were obtained, as the boiler used for the purpose of working the compressing engines appeared unsuitable, and swallowed up an extravagant quantity of fuel, and the whole apparatus was too ponderous for the small amount of work that had to be done. With the simple exception of the cost of working (which, at present, appears to be in excess of steam, although less than horse power), he knew of no motive power so free from imperfection, and so fully under control, as compressed air for tramway and railway lines, as well as for a great variety of other purposes, where a clean and noiseless motive power is required.

Mr. Francis Cobb asked what were the gradients on which the engine had worked, with a train behind it. Some of the gradients on the section of the Metropolitan line, as shown on the diagram, appeared to be as high as 35°.

Colonel Beaumont said the section was exaggerated. The steepest gradient he had worked on the Metropolitan Railway was 1 in 75. The steepest on the line, he believed, was near Snow-hill, where, for a short distance, it was 1 in 40; but the steepest he had taken the engine over was from Praed-street to Edgware-road, which was about 1 in 70 or 75. The steepest tramway gradient he had worked was 1 in 13 at Leeds, in Cooperage-street. There was nothing in the use of compressed air which assisted an engine to mount a gradient, or the reverse, as compared with steam. Steam or air could only supply the motive powers to the wheels, and if the wheels refused to grip, the engine and its load must remain at the bottom of the hill. But there was one point in which it seemed to him that compressed air had a great advantage. If you had a detached engine, and it had to work up steep gradients, such as 1 in 15, or 1 in 18, similar to those which often occurred in tramways, as in the case of the North Staffordshire, you could not get an engine to mount such an incline with a reasonable load behind it, unless it had a weight of about 13 tons, which meant that that weight had to be dragged over the whole line in order to get over the difficulty of that single gradient. Now this difficulty was removed if you could combine the engine and the car. The difficulty of doing this in the case of steam was very great, but with compressed air there was no difficulty whatever, as the reservoirs could be carried on the top of the car, or under the seats. The remarks just made on the Wantage tramways had a very important significance, because they showed that instead of compressed air being ridiculed as a motive power, as was the case a few years ago, it was creeping into public favour, and there was a growing opinion that it was one of the coming powers of the future. The result of the trial made at Wantage, and it was only a trial, showed that compressed air answered all the purposes required of it, and that was an enormous step forward. The only objection was, that Mekarski gave no satisfactory information as to the cost. Now, it was exactly on that point, having seen what the Mekarski engine did in Paris and elsewhere, that he took up the question; and he saw that compressed air could only be used advantageously by avoiding the enormous loss shown in the diagram to arise from reducing the pressure, and supplying the necessary amount of heat by steam-jacketing the cylinder, which were really the alpha and omega of his improvements in the application of compressed air.

Mr. C. B. King said it was not quite correct to state, with regard to the North Staffordshire tramways, that it required an engine weighing 13 tons to get up the incline. It was done with a steam locomotive weighing only 9 tons.\*

Colonel Beaumont said his information was derived from the experience of Messrs. Manning and Wardle, who put on an engine which, he believed, weighed 12 tons empty; at any rate, he was within the mark in saying 10 tons empty, and he contended that that was far too heavy a weight to put on any tramway line.

Mr. Bodmer said the theoretical advantages of Colonel Beaumont's system, over those in which reducing valves were used, must be conceded, but the difficulty which at once occurred to an engineer was, how, with such high pressures, were leakages to be avoided, and he should like to have this explained.

Mr. Houghton congratulated Colonel Beaumont on

the way in which he had compressed his paper, whilst complimenting him on its construction, must he should have liked to hear a little more about construction of the engine. He should like to know how this enormous pressure was dealt with, and whether there would be any difficulty in dealing still greater pressures. If these enormous pressures could be satisfactorily utilised in every-day work should gain advantages we had never hitherto enjoyed for if air could be compressed to a pressure of 12,000 lbs. to the square inch, or even perhaps there would be an enormous gain of power. The peculiarity of this engine seemed to be the introduction of air at an enormous pressure, and the contraction by external means the heat necessary enable it to expand, thus utilising the power contained within it. If the engine worked satisfactorily, seemed to have done so, and would continue to work satisfactorily, there was a very great future before it was evident that certain railways could be worked by this or one or two other means. This instance, the Channel tunnel: they had all had the experience of the defects of ventilation on the Underground Railway, and it was therefore obvious that a tunnel 22 miles in length, the atmosphere would be absolutely pestilential from the products of coal if steam were used. For the tunnel to be a success must be worked either by the pneumatic system of wind behind the train, or by some compressed system, or, lastly, by an electric railway, such as now about being tried in New York. He was glad to know whether these high pressures could indefinitely be utilised, and, further, what was the amount of duty per lb. of coal obtained during use of compressed air.

Mr. Perrett, whilst wishing Colonel Beaumont success, feared that his views as to the application of his system to tramways were rather too sanguine. He had stated the traction at 25 lbs. to the ton, as might be so where the tramway was new and got the road clean, but from some practical experience knew that 45 lbs. to 50 lbs. would be nearer the mark as an average, and, therefore, half the power was at once. His calculations referred to a practical line; and it would be the same thing where the gradient did not exceed 1 in 100 or 1 in 80, because what was lost in going up hill would be gained in going down. But with anything beyond that you required an enormous power in going up, and to put on the brakes going down. On the majority of level tramways, the companies were satisfied with horses, but they wanted more power to work them up over steep places; but in such places, it seemed to him that compressed air was a very good thing. He had in his mind two towns, one of which had an average gradient of 1 in 34, rising in some cases to 1 in 17, for 4,000 yards. In that place he was very anxious to have some mechanical power, but horses could do the work, he, though an engineer, confessed he should prefer them to any mechanical arrangement, if it could be done for the same cost. To his mind, it depended far more on the cost of the engine and on the absence of repairs than on anything else. The cost of repairs with steam was enormous compared to any other item, even fuel. If coals cost 4d. or 5d. a mile, repairs cost 2d. and 2½d. In fact, the driver's wage was more than the coal. Again, the efficiency of the new engine seemed to depend on having a small amount attached to it, but for his part he should much prefer it if this could be dispensed with. Compressed air had many advantages, but it must be compared with the steam-engine of the present day, not with what it was some years ago.

Colonel Beaumont, in reply, said that with regard to the question of leakage, any leakage in the system would be fatal, but they were able now to

\* The gradients upon the North Staffordshire Tramway are exceptionally heavy, ranging from 1 in 12 (for 125 feet) to 1 in 88 (for 1,034 feet).

absolutely bottle tight, with no leakage whatever. No. 2 engine was pumped up when it was at Victoria Docks; about 300 lbs. pressure was about Christmas, and a sufficient amount of air left in it to move the engine only a week to the provisions necessary to prevent leakage. He could not go into the details in such a way, without drawings and diagrams, but the arrangement was similar to that employed by Perkins for a compressed steam-engine. The leakage was prevented by having a series of rings, which acted as a seal for the air, and made the piston all but tight. It was not absolutely tight, it would be so that the second cylinder took up any leakage at first, and he did not believe—although it was without indicator diagrams to say that—there was any serious loss from leakage occurred. And then, the engine which was tried on the Metropolitan Railway remained, so far as its valves, and details, were concerned, precisely in the same condition as it left the makers' yard about a year ago, and it was done, not continuous work, because there was the opportunity for that, but having run 250,000 miles, and required absolutely no oil. He thought, in using these high pressures, wear and tear would be diminished rather than increased. The engine must be powerful when it is a Metropolitan locomotive weighing 40 tons, was running 15 miles an hour the motion admitting the air was so small as to be imperceptible, and the valves by which the high pressure was admitted were hardly as big as the top of the piston. The force stored in the air at this high pressure was so great that it required a very small condenser. At the same time, while perfectly safe precautions were taken, it was no doubt without proper precaution. To see that the valves were absolutely tight, he had a valve made 1 inch by means of an eccentric in the builder's shop, and was kept running for two or three days, and then off and admitting air. When the valve worked it was absolutely tight, so that you could put your eye to it, and look up the piston instant it was lifted the very least, the high pressure coming out exerted so great a force that it would not only tear a piece of paper out of you if you put your hand underneath the piston, but it would tear the flesh off your bones. Yet the length of time these valves had been used had not been able to detect the slightest deficiency in the engine. One gentleman asked for further mechanical details, but, for the sake of brevity, it was impossible to go into that; he said, that after the air had passed the high pressures, there was no difference in principle between an engine and an ordinary piece of machinery. He was asked if it would be practicable to use a pressure of 1,500 or 2,000 lbs. on the inch. He said, that opened a new and most important question, by degrees, he was hoping to occupy. He said that air to be compressed to 15,000 lbs. on the inch: that was done by a gentleman at his object being to supersede the use of blasting in mines. He was turning his head in this direction; but finding this had been once abandoned it, as another gentleman said, he abandoned it. He did not think, but the way in which it was being applied was not practicable, and he was now in communication with people to see if some means could be found by which the use of compressed air could be made safe and dangerous explosives in mines. It was to compress air up to 15,000 lbs. to the inch, and then you came to use it again, no doubt a great deal of trouble would arise. He would say, however, that a pressure of 1,000 lbs., instead of anything enormous, would be looked

upon as a reasonable pressure. For tramway and similar purposes, if you could go a distance of 10 miles with a single charge, there was no great object in going to a higher pressure, but in other cases it would be necessary. It had been suggested to him several times to make a compressed air tricycle, and he intended to try it. He thought it could be done, but, in dealing with these very high pressures, you had to deal with forces which a steam-engine had not to contend with, and consequently when he put the matter into a draftsman's hands, he brought out designs which were incompatible with the light form which a tricycle must take. At the same time he believed it was possible to make a tricycle which should go three miles without recharging, but the solution of the problem depended on the possibility of constructing an engine to work at a pressure of say 2,000 lbs., and which should lose no power by the use of a reducing valve. With regard to the amount of coal needed, the figures would be found in the paper, and that was an all important point with regard to the application of compressed air to tramways. The results of the trials already made were all summed up in the statement that one cubic foot of compressed air would take three tons one mile on a railway; and, with proper arrangements,  $\frac{1}{4}$  lb. of coal would compress one cubic foot of air to 66 atmospheres. Consequently,  $\frac{1}{4}$  lb. of coal consumed under the boilers of a properly constructed compressing engine would take one ton of mile, which about corresponded to the average duty of a coal in a locomotive. It might be said, if that was the case, there would be an end of ordinary locomotives, but that did not follow, because a variety of other considerations came in, especially the extra cost of plant. The Underground Railway could probably be run at about the same working cost, but it would require an increase of 50 per cent. in the value of the plant, and the bulk of the present plant would be rendered useless. Mr. Perrett said he would sooner see the work of tramways done by horses than engines, but in winter, and bad weather especially, the horses had a very hard time of it, and, therefore, he should have rather expected an engineer to say that he would prefer to see the horses doing some other kind of work. But that point did not really concern an engineer; because he was quite certain that no system of mechanical traction had any chance of superseding horse-power unless it showed a saving. In that view the offer he was prepared to make was to take any tram line and tract it at 6d. per mile, instead of 7d., which represented the average cost of horse traction, as would be seen by an examination of the accounts of the North Metropolitan Tramway Company. That would show a saving of 1d. a mile, which would add 25 per cent. to the profits. The same gentleman seemed to think there was a difficulty about a compressed air-engine mounting steep gradients, and, if that were the case, any engineer would be a lunatic to think of introducing it; but the fact was, of all lines he should prefer to work with compressed air, would be one with a steep gradient; because the cost of horse flesh increased in proportion to the gradient, and so did the difficulty of working with a steam locomotive; simply because the boiler was tipped up at an angle, and, consequently, laid bare the tubes. They all knew the danger and difficulty which attended any portion of the tubes of a locomotive getting burned, because the cost of it depended principally on keeping the boiler in repair. This was so important that, in some cases, where steep gradients had to be encountered, a vertical boiler was used, but that was always an unsatisfactory arrangement. Another difficulty was that it was quite impossible for a steam locomotive to proportion its weight to the work it had to do. The boiler had to be capable of supplying the cylinders with steam, in proportion to whatever the maximum draw might be, and the maximum draw depended on the maximum incline

the engine had to ascend. With compressed air this difficulty did not arise. You could run up an incline of 1 in 14, with a comparatively small supply of air in the reservoir, because you could take in a fresh supply either at the bottom or the top of the incline. Consequently, if you were working a tramway line, where the incline for a short distance was very severe, it would need no special arrangement beyond a provision at the bottom of the incline for giving the engine a fresh supply of air.

The Chairman then proposed a vote of thanks to Colonel Beaumont for his interesting paper, which was carried unanimously.

## MISCELLANEOUS.

---

### A NEW TELEPHONE.

A paper "On the Conversion of Radiant Energy into Sonorous Vibrations," was read before the Royal Society last week, by Mr. W. H. Preece, the electrician to the Post-office. The remarkable discovery of Messrs. Graham Bell and Sumner Tainter that the rapid intermittent incidence of rays of light on discs of hard substances produces sonorous vibrations has attracted very much attention, and has excited much physical work to solve an unexpected problem. The advocates of the emission theory of light have striven for 200 years to obtain such a proof of their theory and have failed. Why have Bell and Tainter succeeded, or have they succeeded at all? May not their phenomena be due to some other cause than to the incidence of light? It was suspected by many that it was a heat effect, and not a light one at all. M. Mercadier, in Paris (*Comptes Rendus*, Dec. 6th, 1880), and Professor Tyndall (*Proc. R.S.*, Jan. 3rd, 1881) have placed this beyond the region of doubt, and now Mr. Preece has completed the chain of evidence by a careful and elaborate inquiry into the cause of the phenomena. In the first part of his paper he has shown that ebonite and india-rubber, though opaque to the light rays, are remarkably diathermanous or transparent to the heat rays, and therefore that radiant heat can act through screens of those materials. Indeed, ebonite is shown to be almost perfectly transparent to radiant heat, while it is absolutely impervious to light. He next shows by experiments made on very delicate apparatus that no more vibrations than six per second can possibly be produced by the direct impact of heat waves causing expansion of the mass of the disc, and therefore that the Bell-Tainter effect is not due to the absorption of heat changing the volume of the hard substance experimented upon. He next inquires whether the effect observed is due to a molecular pressure similar to that which produces the rotation of the radiometer, for this being a mere surface action, the element of time is eliminated. Many experiments are described which were made with discs of various kinds in different ways, but the results were so unsatisfactory and variable that the question was raised whether the discs vibrated at all. By the aid of microphones and specially constructed chambers, it is proved clearly that the undulations are those of the contained air, and not of the discs. In fact, the sounds were intensified by removing the discs. Moreover, the effects were materially assisted by coating the sides of the containing vessel with a substance highly absorbent of heat, such as the carbon deposited by burning camphor. It is next shown that the effects are dependent on the number of heat rays that pass through the discs, and not on those that are incident on them, and that the greater the absorbent character of the air or vapour contained in the case, the more intense the sounds emitted. All these results are repeated and shown with ordinary flasks lampblackened on their

exterior and interior. Finally it is shown that a time element introduced, and that the loudness note emitted depends not only on the rapidity with which the contained air absorbs the radiant heat but also on the rapidity with which it gives heat to the sides of the case and the exit of it. It varies also with the form of the space, and with the character of the vapour, and with the diathermancy only. The effect being thus due to radiant heat absorption by suitable surfaces, it was next ascertained if a spiral of wire be completely enclosed in a blackened case, sounds were emitted when an electric current was rapidly and intermittently transmitted through the wire, and, moreover, that when the currents were produced by a proper microphone, articulate speech was reproduced. These phenomena are simply effects of radiant heat, and are due to the changes of volume in absorbent vapours, produced by the absorption of the heat in a confined space. All the varied experiments which Mr. Graham Bell performed when he was recently in Europe with solids, liquids, gases, with tubes, flasks, and discs, are thus within one simple explanation, and are due to the influence of degraded heat rays on vapours. The final result of this inquiry has been only to unravel an exceedingly interesting problem, but to produce another form of light based on a new principle.—*The Times*.

### LUMINOUS PAINT.

The manufacture of this paint, which was brought prominently into public notice by Mr. Spottiswoode, appeared in our paper upon it last year (*Journal of the Society of Arts*, vol. xxviii., p. 389), is stated to be progressing so far that the manufacturers having succeeded in considerably reducing the cost of production, and consequently the cost at which the article can be supplied. One of the more important applications of this material is for the whitening of ceilings. When the paint was first made, it was proposed to utilise it in this manner, but one difficulty doing so was the high cost of the material, and the second was that it could only be applied with a brush and not in the ordinary manner of a lime wash. It seems, however, now to be no difficulty in its application, and several small rooms have been successfully treated. Mr. Spottiswoode, President of the Royal Society, has had the ceilings of some rooms in his house covered with it, and at the company's offices in Aldermanbury has also a room with a luminous ceiling. This is better than might have been anticipated. It appears as if it were lighted with bright moonlight, except that no portion of it is brighter than the rest, as is, of course, with moonlight, where the moon is actually full. Even on coming into the room out of the daylight there is no difficulty in seeing sufficiently well to walk about the room, take objects from the table, &c., and after a few minutes the eyes become sufficiently accustomed to the luminous surface, at all events, to see the time by a watch face. Another novel application is to lanterns, if such an expression can be used. They are formed of oblong tin cases, the outside of which is coated with the paint. Upon hot water being poured into the inside, the luminosity of the paint is to a very high degree. It is well known that on a surface covered with it by magnesium wire, a powerful illuminator, the great brilliancy of the light immediately dies down in a very short time on a comparatively dimly-lighted surface. The hot water brings out the same amount of brilliancy.

maximum as long as the water remains. Little water be placed at the bottom of a tin may be aroused by shaking the same all sides of it. As it dies down it rises it up again. This form appears in the ordinary plan of having a sheet of lead with a glass and set in a frame like that. These appear to be the principal applications noticed in Mr. Heaton's paper above. The paint is also used to a considerable extent in match-boxes, statues, brackets, &c., as these can only be included in the thing scientific toys.

## CORRESPONDENCE.

### INDIAN RULE IN INDIA.

an opportunity of being present at Mr. Maclean's lecture on "The Results of the Census of India," I trust you will allow me to make on one branch of his subject, which requires further investigation—the question there is, or is not, danger in the over-population in India.

Mr. Maclean compares the population per square mile in India with the other countries, and shows that, whereas to the square mile, Belgium has 451; Wales, 389; Tuscany, 377; the Netherlands, 289; Great Britain and Ireland, 249; and Germany, 193. This is a useful comparison as far as it goes, but it is rather than the edge of the subject. To suggest to Mr. Maclean that it is important to give your readers the following as regards each country:—Population in each country depending on subsistence.

State of the agricultural condition and especially whether the people have the means of maintaining the fertility of

of the probable rate of increase of the

of the culturable unoccupied lands. State of the population, and whether it is increasing or decreasing.

If necessary further investigation is, I think, at, as regards the first point, I once had writing on the danger of over-population in India with Belgium. I then found that the population of India exceeds that of Belgium, taking into consideration the vast area of India, I found the agricultural population per square mile so much exceeding twice the population of Belgium, that it certainly cannot be quite safe to say that the agriculture of India is, to the available square mile, that of Belgium. In other words, from the bare statements of statistics, we have twice the pressure of population in the latter country has practically a pressure that of Belgium; and I feel quite sure on other points I have mentioned were considered, the danger of over-population in India is probably greater than would, at first, be supposed.

Mr. Maclean has another test, though by his way it would seem to be the only one needed. "The controversy," he says, "about over-

population, resolves itself into the question—Are the rates of wages relatively higher or lower in proportion to the prices of food grain, than they were ten or twenty years ago?" Is not this, to say the least of it, a singular way of attempting to solve, or, I should perhaps rather say, shelve a most difficult problem? Let us, for the sake of argument, admit that the rates of wages in India are universally relatively higher in proportion to the prices of food grain than they were ten or twenty years ago, and let us ask what then? It is proverbially difficult to prove a negative, and Mr. Maclean has thrown upon himself the task of proving a most formidable negative. He must prove that the material increase of the population will not ultimately destroy his test; in other words, will not have the effect of again lowering the rate of wages relatively to the price of food, down to the rates which prevailed ten or twenty years ago.

Let me notice another of Mr. Maclean's conclusions. He thinks that because the Bengali refuses to emigrate, he must therefore be, "on the whole, tolerably well-satisfied with his lot." Are the Irish cottagers, in the west of Ireland, tolerably well-satisfied with their lots, because they are disinclined to emigrate? I am afraid that this statement will no more bear examination than one to be met with some sentences further on, where Mr. Maclean informs us that the "English labourer, earning his twelve to eight shillings a week, is compelled to live on animal food and strong drink." I have no doubt that he only wishes he was put under any such compulsion, and that his wage were high enough to admit of his living so luxuriantly.

ROBERT H. ELLIOT.

Clifton-park, Kelsae, N.B.

## GENERAL NOTES.

**International Wool Exhibition at the Crystal Palace.**—In connection with this Exhibition, the Clothworkers' Company offer the Company's Gold Medal for the following subjects:—(1) For the best piece-dyed Navy blue cloth or worsted coating; (2) for the best Navy blue cloth or worsted coating, dyed without the use of indigo; (3) for the best scarlet cloth, dyed without the use of cochineal; (4) for the best 10-lb. sample of scarlet woollen yarn, used for shirtings, dyed without the use of cochineal; (5) for the best piece of bleached flannel, the bleaching to have been affected without the use of sulphuric acid in any form; also for various articles composed entirely of English wool (i.e., wool grown in Great Britain and Ireland), and for the best apparatus for scouring and cleansing worsted coatings, previous to dyeing. Preference will be given to that which most thoroughly combines efficiency with simplicity and economy in working. The Drapers' Company have voted a sum for various special prizes, and other of the City Companies identified with the textile industries propose doing the same; these are in addition to the medals and certificates to be given by the Directors of the Crystal Palace Company.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MARCH 23.—"The Increasing Number of Deaths from Explosions, with an Examination of the Causes." By CORNELIUS WALFORD, F.S.S. Professor ABEL, F.R.S., will preside.

MARCH 30.—"Recent Advances in Electric Lighting." By W. H. PREESTER, M.Inst.C.E. C. W. SIMMONS, F.R.S., will preside.

APRIL 6.—"The Discrimination and Artistic Use of Precious Stones." By Professor A. H. CHURCH, F.C.S. Sir PHILIP CONLIFFE-OWEN, K.C.M.G., C.B., C.I.E., will preside.

APRIL 27.—“Five Years’ Experience of the Working of the Trade Marks’ Registration Acts.” By EDMUND JOHNSON.

Dates not yet fixed :—

“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works).

“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS.

#### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o’clock :—

APRIL 5.—“Canada; the Old Colony and the New Dominion.” By E. HEPPLE HALL.

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o’clock :—

MARCH 24.—“The Future Development of Electrical Appliances.” By Prof. JOHN PERRY. LATIMER CLARK, F.R.G.S., will preside.

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Professor A. K. HUNTINGTON.

#### INDIAN SECTION.

Friday evenings, at eight o’clock :—

MARCH 25.—“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P. ANDREW CASSELS, Member of Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

#### CANTOR LECTURES.

Monday evenings, at eight o’clock :—

The Third Course will be on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

##### *Syllabus of the Course.*

##### LECTURE III.—MARCH 21.

Use of magneto- and dynamo-electric machines for electric lighting. Electric lighting by means of the arc.

##### LECTURE IV.—MARCH 28.

Subdivisions of the electric current. Incandescent lamps. Luminous effects of electric currents in a vacuum, and in various gases.

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Four Lectures.

April 4, 11; May 2, 9.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

#### ADMISSION TO MEETINGS.

Members have the right of attending all the Society’s meetings and lectures. Every Member can admit *two* friends to the Ordinary and Sectional Meetings, and *one* friend to the Cantor Lectures. Books of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

#### MEETINGS FOR THE ENSUING

MONDAY, MARCH 21ST...SOCIETY OF ARTS  
Adelphi, W.C., 8 p.m. (Cantor Lecture)  
G. Adams, “The Scientific Principles of Electric Lighting.” (Lecture III.)  
Royal United Service Institution, Whitehall  
Vice-Admiral J. H. Selwyn, “A Hydraulic Propulsion.”  
Institute of Surveyors, 12, Great George-street, 8 p.m. Resumed discussion on Mr. paper, “Sanitation, as an important factor in House Property.”  
Medical, 11, Chandos-street, W., 8½ p.m.  
Asiatic, 22, Albemarle-street, W., 8 p.m.  
Victoria Institute, 7, Adelphi-terrace, W., by Mr. J. F. Bateman.  
London Institution, Finsbury-circus, E.C. R. Bentley, “Fungi.”

TUESDAY, MARCH 22ND...Royal Institution, Albert-street, 8 p.m. Prof. E. A. Schäfer, “The Blood Medical and Chirurgical, 53, Berners-street, W., 8½ p.m.  
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. David Phillips, “Endurance of Iron and Mild Steel w Corrosive Influences.”  
Anthropological Institute, 4, St. Martin’s-place, 8 p.m. 1. Prof. W. H. Flower, “Artificial Skulls from Mallekolo.” 2. Mr. Jose Ethnological Bearings of the terms and Romo.”  
Royal Colonial, the Grosvenor Gallery, 1, Bond-street, W., 8 p.m. Mr. W. M. “Imperial and Colonial Partnership in Royal Horticultural, South Kensington,

WEDNESDAY, MARCH 23RD...SOCIETY OF ARTS  
Adelphi, W.C., 8 p.m. Mr. Cornelius Increasing Number of Deaths from an Examination of the Causes.”  
Geological, Burlington-house, W., 8 p.m. Parkinson, “The Upper Greensands of the Isle of Wight.” 2. Mr. Clem Flow of an Ice-sheet, and its Connect Phenomenon in Britain.” 3. Dr. R. “Soilcap Motion.”  
Royal Society of Literature, 4, St. Martin’s-place, 8 p.m. Mr. C. F. Keary, “The Spurious in the Eddaic Mythology. I. and of the Other World.”  
Royal College of Physicians, Pall-mall E (Croonian Lectures.) “Influence of upon the Nervous System.” (Lecture

THURSDAY, MARCH 24TH...SOCIETY OF ARTS  
Adelphi, W.C., 8 p.m. Prof. John Perry Development of Electrical Appliances.  
Royal, Burlington-house, W., 4½ p.m.  
Antiquaries, Burlington-house, W., 8½ p.m.  
London Institution, Finsbury-circus, E.C. Ernst Pauer, “The History of the Instrumented Musical Lecture.”  
Society for the Encouragement of Fine Arts, 8, Pall-mall, 8 p.m.  
Royal Institution, Albemarle-street, W., 8 p.m. Statham, “Ornament Historically considered.” (Lecture II.)  
Inventors’ Institute, 4, St. Martin’s-place  
Royal Society Club, Willis’s-rooms, St. 6 p.m.

FRIDAY, MARCH 25TH...SOCIETY OF ARTS  
Adelphi, W.C., 8 p.m. (Indian Section)  
Campbell, “The Tenure and Cultivation of Land in India.”  
Royal College of Physicians, Pall-mall E (Croonian Lectures.) “Influence of upon the Nervous System.” (Lecture I.)  
Royal United Service Institution, Whitehall  
Lieut.-Col. Lonsdale A. H. Hale, “Out by the Systems followed in Continents.”  
Royal Institution, Albemarle-street, W., 8 p.m. A. Buchan, “The Weather and the Haze.”  
Quekett Microscopical Club, University-street, 8 p.m. Mr. J. G. Waller, “Olfaction: Sponge make the Burrows?”  
Clinical, 33, Berners-street, W., 8½ p.m.

SATURDAY, MARCH 26TH...Ladies’ Sanitary Association of the Society of Arts, 63, Richardson, “Domestic Sanitation or Hygiene.” (Lecture VI.)  
Physical, Science Schools, South Kensington  
Geologists’ Association, University College, 23, Gower-street, W., 6 p.m. Visit to the Museum of Practical Geology, under the direction of Mr. F. R. Royal Botanic, Inner-circle, Regent’s-park  
Royal Institution, Albemarle-street, W., 8 p.m. R. Haweis, “American Humourists.”

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,479. Vol. XXIX.

FRIDAY, MARCH 25, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

Third lecture of the third course was delivered on Monday, 21st inst., by Professor W. G. B. F.R.S., on "The Scientific Principles in Electric Lighting." The lecturer described the use of magneto- and dynamo-electric machines for electric lighting, and electric lighting systems of the arc. The lecture was fully illustrated by apparatus and lamps kindly lent following:—Mr. Berly, Jamin candles; British Electric Light Company, two Gramme lamps, Brookie lamp, and Serrin lamp; Brush Light Company, Brush lamp; Mr. Latimer Clark, Contin lamp, Wilde lamp, and models; Mr. W. A. Bürkin machine and armature, and dynamo lamp; Messrs. Elliott and Co., Trowbridge electro-dynamometer; Messrs. Robey and Co., of Lincoln, a ten-horse power steam engine; Dr. Siemens, F.R.S., early dynamo lamp, pendulum lamp, electro-dynamometer lamp; Société Generale d'Electricité, arc lamp. Diagrams were lent by Dr. W. G. B. F.R.S., and Mr. Shoolbred. The lecture will be published during the summer.

## DOMESTIC ECONOMY CONGRESS.

Meeting of the General Committee was held on Monday, 22nd. Present:—Lord ALFRED S. D. LL (in the chair), Miss Rose Adams, the Hon. Mrs. of Airlie, Mrs. G. C. T. Bartley, Lady Darnley, Miss Clive Bayley, Miss Bidder, Mr. Buckton, Miss Buckton, Lady Cole, Miss King, Lady Dorothy Neville, Lady Russell, Miss Wetton; Sir Henry Cole, Major-General Cotton, C.S.I., Rev. J. P. Price, and Rev. Newton Price, with Mr. H. Wood, Secretary. The Committee considered and revised the Programme for the

## ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1881, early in May next. This medal was struck to reward "distinguished merit in promoting Arts, Manufactures, or Commerce," and has been awarded as follows:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great service to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially, by the abolition of passports in favour of British subjects."

In 1866, to Professor Faraday, D.C.L., F.R.S., for "discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (now Sir) Joseph Whitworth, F.R.S., LL.D., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Ferdinand de Lesseps, "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (now Sir) Henry Cole, C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the development of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to the Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential service in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy, and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S., "on account of the signal services rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science and industrial pursuits."

The Council invite members of the Society to forward to the Secretary, on or before the 23rd of April, the names of such men of high distinction as they may think worthy of this honour.

#### HOUSE SANITATION.

The Council offer the following Medals for the best Sanitary Arrangements in Houses built in the Metropolis, the plans of such arrangements to be exhibited in the Society's Rooms, Adelphi, in June, 1881, and to be sent in on or before 12th May, 1881:—

1. One Silver Medal for the best sanitary arrangements, carried out and in satisfactory working, in a house let out in tenements to artisans, for which a weekly rental is paid.

2. One Silver Medal for the best sanitary arrangements, in actual working, in a house of the yearly rental of £40, or less, to about £200 in value.

3. One Silver Medal for the best sanitary arrangements, in actual satisfactory working, in a house of the yearly rental value of £200 and upwards, to any amount.

4. The houses must be open to the inspection of the Judges, who, in considering their award, will be guided by the suggestions of plans for main sewerage, drainage, and water supply, made under the Public Health Act, 1875. The houses must have been in actual occupation within the last three months, and a Certificate must be given by the occupiers, on a printed form, stating the satisfactory working of all the sanitary arrangements, such form to be obtained at the Society of Arts.

5. The houses may be old, fitted with sanitary arrangements, or may be new, and must be within the metropolitan area of Works.

6. The sanitary arrangements must be in good conditions for good water supply, draining, and ventilation of the house, and taken against frost.

7. The medals may be awarded to the owner of the houses, or the lessees, or the occupiers.

8. The plans must consist of a ground plan, and sections, to the scale of not less than 1 inch to 10 feet; details of not less than 1 inch to 1 foot. The plans may be accompanied by descriptive statements.

9. The names of the architects, and of the sanitary engineers who directed the execution of the arrangements should be given, and will be awarded to those whose plans are the most successful. Medals.

## PROCEEDINGS OF THE

### SIXTEENTH ORDINARY MEETING

Wednesday, March 23rd, 1881; P. M.  
ABEL, C.B., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Atkinson, John, Tosti, Falsgrave, Scarb  
Bacon, George Washington, F.R.G.S.  
W.C.

Black, William, South Shields.  
Lorimer, William, Messrs. Dubs and Co  
Russell, William J., Ph.D., F.R.S., 34,  
ton-terrace, N.W.

The following candidates were balloted for and duly elected members of the Society

Appleby, Francis James, The Rowans,  
S.E.

Bayley, Sir Edward Clive, K.C.S.I.  
Wilderness, Ascot.

Brass, John H., Wentworth-house,  
Chelsea, S.W.

Brothers, William, Meadow-head-hill,  
Blackburn.

Cahen, Albert, 7, Bayswater-hill, W.

Godfrey, William Bornard, 54, Regent's-park,  
Jenkinson, Edward George, 26, Palace-gate,  
Kensington, W.

Ogg, Surgeon-Major G. S. W., 8, St. John's-street,  
Hampstead, N.W.

Roper, Richard, 143, Lewisham High-road,  
S.E.

Staight, Daniel George, 63, Tulse-hill, S.W.

White, Frederick Anthony, Kinross-house,  
road, S.W., and 85, Gracechurch-street, E.C.

The paper read was—

**CREASING NUMBER OF DEATHS FROM EXPLOSIONS, WITH AN EXAMINATION OF THE CAUSES.**

Cornelius Walford, F.I.A., F.S.S.,  
Barrister-at-Law.

be fully understood, at starting, that I propose to approach this topic from a different view. Observations, conducted over a series of years mainly for statistical purposes, have impressed upon my mind the conclusion that explosions are far more numerous than they have been at any previous period.

This fact established, and the reasons being plain, it will then remain for science to find remedies in mitigation, or to declare why no more can be done.

It is necessary to seek far for the causes of the increasing number of explosions in modern times, as forces are being constantly brought to bear to meet the requirements of our manufacturing and mineral industries. Steam itself, which we have ceased to regard its application as a modern invention—regarded from the point of its practical application. It is, indeed, since the Marquis of Worcester first used the steam-engine in his "Century of Invention" but it is very little more than one hundred years since Watt's engine was first used as a motive power in a manufactory (1775); it is only in the present century that steam navigation has become a practical fact, and that steam has been used for the purpose of locomotion on land. One of the first fixed steam-engines in London was that used for the purpose of pumping out the water from the mines, as the *Times* newspaper, in 1814. The application of steam to the purpose of locomotion may be said to have witnessed the application of steam to our daily life.

With this, it is not so much to the effects of steam as to trace the increasing risk of explosion. Steam has long played an important part, its use extending over some five or six centuries. The invention falling within the range of the last century, has been, perhaps, on the whole, the deadly agent of destruction—in the case of intentional explosions—than gunpowder; and chemical compounds of almost endless kinds, finally, mineral oils, make up the sum of the evils which in the present day prove so dangerous to life and property.

In attempting to compare one period with another, on the matter of destructiveness, we are often misled by the want of requiring statistical records; for the number is always more or less misleading, and the want of comparison in the sense of the word.

There are practically no statistics as regards the returns resulting from the operation of the Act of 1836, for the registration of deaths. But this Act only applied to the kingdom (England and Wales), and the causes of deaths were not, as a rule, published earlier than for the year 1852, not then in such a manner as to be of any use for the purpose I now have in view.

**DEATHS CAUSED BY EXPLOSIONS.**

The first report of the Registrar-General, the year 1840, shows the number of deaths from explosions in certain selected districts, the metropolis, Birmingham, Manchester and

Salford, Liverpool and West Derby (adjoining), the mining districts, and the agricultural districts of Norfolk and Suffolk, were returned as being 41 in the year 1838, all occurring to males. The proportion of deaths from explosions, scalds, burns, and lightning (all classed together), to 100,000 deaths from all causes was found to vary in different districts of the kingdom from 14.6 in the metropolis to 20.7 in Norfolk and Suffolk; 28.3 in Manchester, Liverpool, and Birmingham, up to 38.8 in the mining districts.

In the seventh report of the Registrar-General, it is shown that the deaths from explosions, in the year 1840, were at the rate of 19.4 per million of the population, viz., males, 19; females, 4.

For the next 12 years, these national records are silent on the subject of deaths from explosion. This was not because the question was overlooked, but the rather that a process of elaboration was being devised, whereby the violent deaths in England and Wales should be rendered capable of scientific classification. The arrangement propounded in the nineteenth report was to classify the total violent deaths under six leading divisions. 1. Connected with railways; 2. Connected with mines (coal and metals treated separately); 3. Mechanical injuries; 4. Chemical injuries; 5. Asphyxia (suspension of respiration); 6. Violence not otherwise classed.

Several of these divisions enumerated deaths from explosions. The first from explosion of boilers; the second (in each of its sub-divisions), explosions of fire-damp, and also of boilers. The third, boiler explosions (very numerous); the fourth, explosions of chemical compounds. Thus, in the five years, 1852-6, the deaths from explosions were as follows, under the several causes mentioned by the Registrar:—

	Males.	Females.	Total.
<b>1. RAILWAYS:—</b>			
Explosion of Boiler .....	12	—	12
<b>2. MINES (COAL):—</b>			
Explosion of Fire-damp .....	998	1	999
"    Boiler .....	16	—	16
"    (METAL):—			
Explosion of Fire-damp .....	3	—	3
"    Boiler .....	6	—	6
<b>3. MECHANICAL:—</b>			
Explosion of Boiler .....	149	15	164
<b>4. CHEMICAL:—</b>			
Explosion of Gunpowder .....	72	16	88
"    Camphine .....	—	1	1
"    Gases .....	27	2	29
"    Naphtha .....	7	—	7
"    Sulphur and .....	24	—	24
Nitrate of Silver .....	—	6	6
Explosion of Fireworks .....	28	—	28
Here we have a total of .....	...	...	1,373

Giving an average of 274.6 deaths from explosions in England and Wales for each of the years embraced in the period under observation.

It now becomes possible to commence the construction of a table, showing the annual deaths from explosions in England and Wales, but not continuously, for the returns in a corresponding

last reviewed were omitted during the -62, since which last date, however, inous.

meration which recommenced in 1863, eluded some items which did not pre- ear, as, for instance, under "Coal xplosions of Sulphur," and "Explo- tated how," these latter not including ing from "Blasting," which are sepa- ed, but are not included in my table; er Chemical are added "Gun-cotton," m," "Tar Boiler," "Manner not stated."

—SHOWING THE DEATHS FROM EXPLOSIONS NG DURING THE PERIOD 1852-1879 (ENGLAND ALES).

9	450	12	462	38.2
	6,480	324	6,814	
Average of the 22 years	295.0	14.8	309.8	

It will be seen that there are considerable fluctuations in the annual number of deaths from explosions. This was to be expected, from the nature of the case, but they will be found mainly to arise from explosions of fire-damp in coal mines, with occasional fluctuations from other causes. In view of elucidating this point, I have prepared the following table, showing the annual deaths from the principal classes of explosions, as—1, fire-damp; 2, boiler explosions; 3, chemical explosions; 4, un- named causes (embracing both sexes). This at a glance gives an indication of the cause of the situation in any one year or at particular periods. One or two of the more prominent cases of fluctuation, shown in Table B., may be made plain by the following notes. Thus—

In 1867. There were 320 male deaths, returned as "Explosion, not stated how;" but most of these were from fire-damp.

Under chemical injuries, were included 30

deaths by "steam;" probably steam, consequent upon explosion in 1871. There were 63 deaths due to "gunpowder" explosion—these were classed under "chemicals."

TABLE B. — SHOWING THE ANNUAL DEATHS FROM EXPLOSIONS, CLASSED UNDER FOUR DIVISIONS—1852-79—(ENGLAND AND WALES).

Year.	Fire-damp.	Boilers.	Chemicals.

Average of the 22 years	187.2	37.4	70

But apart from such minor fluctuations there is a clear lesson to be learned, and it is this—that while explosions show an almost constant fluctuating decrease of loss from explosions of chemicals, although fluctuating in the little doubt that this latter is a danger to life and property.

#### WIDER RANGE OF

But, on the whole, these tables, while they show the deaths resulting from explosions in the divisions of the United Kingdom—do not convey the consequences annually.

For the other divisions of the United Kingdom and Ireland, the Registrar-Generals have not yet published the deaths resulting from explosions, comprehended in the "Violent deaths."

#### NON

The first point to be noted is that the deaths and necessarily the injuries. Deaths

a very large proportion of the injuries in explosions do not terminate fatally. The experience of the Accident Insurance—which is that 100 non-fatal to each fatal injury—we have an annual average of 30,970 injuries to, resulting from explosions of various kind and Wales alone.

His last estimate does not measure the extent of the resulting evils, for in the persons killed, there are the widows and families left unprovided for to be brought

And here it becomes important to consider, at the time of death, of the victims. Taking one year, 1879, as an example, the facts were as follows:—Of the total there were at ages under 15, 52; at 15-20, 25, 69; 25-35, 136; 35-45, 74; 45-65, 19; 65-75, 2; 75-85, 1. So great a majority of instances, the persons are families dependent upon them.

#### PROPERTY DESTROYED.

At present exists no means of even estimating the exactitude of the amount of property destroyed by explosions. It is somewhat, as witness the consequences of the explosion, 1854 (referred to, in detail, in "Mineral Stores," later in this paper); and in the case of the Flour Mills, 1878 (spoken of in the report, under title, "Flouring Mills,"

But this point will be again referred

#### LOCALITIES OF EXPLOSIONS.

For completeness, it is desirable, at this time, to give the localities of explosions, as in the records of deaths. For the purposes of local death registration, England and Wales are divided into 11 geographical registration districts as follows:—

Western England.	VII. North Midland.
	VIII. North-Western.
Eastern. England.	IX. Yorkshire.
	X. Northern Counties.
	XI. Monmouthshire and Wales.

As in 1879 were spread over these districts as follows:—

v.	vi.	vii.	viii.	ix.	x.	xi.	
5	31	5	27	35	7	331	— Total 462.

On of collieries subject to explosion, and, determines the divisions wherein the number of deaths from explosions occur.

#### RECORDS OF EXPLOSIONS, AND THEIR CAUSES.

Now, I believe, exhausted all the available statistical information, I still feel that the results presented are by no means adequate. The importance of the inquiry which I have taken; and it, therefore, becomes necessary to consider what further process of elucidation can be made available. This can, I think, be accomplished by reviewing the chief "explosions" in separate detail; and I proceed upon this new line of inquiry. The branches of inquiry in alphabetical

order. I cannot pretend to make some of the sections exhaustive; they must be regarded as illustrative only.

#### CHEMICAL COMPOUNDS AND PROCESSES.— ILLUSTRATIVE CASES.

1854.—October 6. Gateshead and Newcastle.—Fire broke out in a worsted manufactory adjoining a bonded warehouse. This latter was considered to be a double fire-proof structure, being supported on metal pillars and floors, and lined throughout with iron-sheeting. In this building was stored a large variety of chemical stores, and amongst these 47 tons of sulphur in one vault, covered with a tarpaulin to protect it; but on this tarpaulin was placed 45 tons of nitrate of soda. There was no gunpowder, charcoal, saltpetre, or naphtha stored there. The fire in the worsted warehouse caused the brickwork of the bonded warehouse to crumble away, and, ultimately, nothing remained on one side but the red-hot skeleton of the building. Some workmen, who had been engaged with nitrate of soda, predicted that it would explode, but this view was not generally entertained. Finally, one of the most terrible explosions of which we have any record in this country, occurred. By means of it the shipping on the River Tyne became ignited, and the fire was thus carried across the river into Newcastle, where many houses were burned, and others seriously damaged by the explosion. The property destroyed was estimated to have been of the value of £600,000, the loss mostly falling upon insurance offices.

An inquiry into the cause of the explosion was instituted, and in view of making its results clear, it is necessary to state that the chemical stores in the warehouse, beyond those already named, consisted of guano, alkali, fullers'-earth, ammoniacal charcoal, potash, yellow ochre, bone-ash, arsenic, zinc, iron, lead, magnesia, alum, and coal-tar. Mr. Hugh Lee Pattison, chemical manufacturer, being called as a witness, said he was of opinion that none of the substances named were explosive, *per se*; that no two would be explosive by being rudely mixed together; perhaps hardly any three of them would become explosive by being so mixed. He had made experiments for this occasion, and had melted nitrate of soda, and when perfectly fluid and red-hot had poured into it melted brimstone. There was produced certainly intense heat, but no explosion. Another element was therefore wanted, and that element was water. There was, he said, abundant evidence that when water comes in contact with intensely heated and melted saline matter, instant explosion takes place. It would be essential for the amount of water to produce its full effect, that it should fall upon the tested saline mass at once. A pint of water would cause a loud explosion. He of course thought it very unsafe to have such a quantity of combustible matter so placed as had been the case here; but he might have added that it was the efforts of the fire-brigade to extinguish the fire, by the application of water, that caused the explosion.

1867.—Fire occurred on premises where the business carried on was that of extracting oil from shoddy, the process being the following:—The shoddy is placed in an "extractor," into which is pumped from below bi-sulphide of carbon; this,

rising through the shoddy, disengages the oil, which flows off through a hole in the top of the extractor. The bi-sulphide is next drawn off, and steam introduced, which carries off the residue of the bi-sulphide and oil remaining in the extractor into a still, where they are separated. The vapour which thus passes from the extractor is condensable at a temperature of about 109° Fahr. This vapour is highly inflammable, and, when mixed with air in the proportion of 1 to 15, is explosive. In the present case there was a leakage in the gaskin (or packing of canvas), which lies between the lid and rim of the extractor, coupled with a stoppage in the pipe between the extractor and the still. The vapour, escaping through the hole, ignited at the lamp, and set fire to some bags lying near; finally, the vapour becoming sufficiently mixed with the air, exploded, and caused considerable damage to the building, out of which arose the important insurance case, *Stanley v. Western Insurance Co.*, 1868. This is a type of a large class of explosions in connection with chemical processes.

1878.—In Paris, on 15th May, this year, an explosion of chemical compounds occurred on the premises of a toy manufacturer, in the Rue Beranger, a leading thoroughfare of the city, whereby nearly 100 persons were killed or injured, and much property was destroyed.

1879.—Serious explosion in Newark, New Jersey, United States. The process being carried on was that of manufacturing celluloid. This substance is a species of solidified collodion, produced by dissolving gun-cotton (pyroxylin) in camphor, with the aid of heat and pressure. The gun-cotton is ground in water to a fine pulp, in a machine similar to that used in grinding paper pulp. The pulp is then subjected to powerful pressure in a perforated vessel, to extract the bulk of moisture, but still leaving it slightly moist for the next operation. This consists in thoroughly incorporating finely comminuted gum camphor with the moist gun-cotton pulp. The proportions employed are understood to be one part by weight of camphor to two parts by weight of pulp. After final pressure to expel the remaining moisture, the substance is cast in moulds to the form required, and constitutes an excellent substitute for ivory. It is now being used, combined with linen, for the manufacture of cuffs, collars, and shirt fronts, with many other articles of common use. It is liable to explode in several of its stages; and it may be regarded as presenting one of the newest dangers with which we are familiar. In the particular instance before us, how the materials ignited—whether by spontaneous combustion or otherwise—is not known. The substance is highly inflammable, as well as explosive, and demands the aid of science to provide an antidote for its dangers.

In the processes of distilling ardent spirits, carried on largely in thickly populated districts, there is always the risk of explosion, either (1) in the process retracting the crude spirit from the substance operated upon; or (2) in refining the spirit so obtained, especially the latter. But here the aid of science has been rendered largely available.

It seems desirable to give some further details regarding explosions of this class, hence I have prepared the following table:—

TABLE C.—EXPLOSIONS OF CHEMICAL COMPOUNDS OTHERWISE THAN GUNPOWDER WORKS.

1837.	June 24....	At Blaina Ironworks (Monmouthshire); much damage to property accumulated in a distillery works. (See 1855.)
1842.	May 6....	Hodge's Distillery. Explosive spirits, a large quantity destroyed.
1847.	July....	Hall's Gun-cotton Factory, Faversham; great destruction of property to have originated through premises.
1854.	Oct. 6.....	Chemical stores in bonded warehouse. Details already given.
1855.	Dec. 14....	Explosion at iron furnace, Billingham; about six tons of molten cinders were blown about; 1 killed. (See 1837.)
1867.	Dec. 17....	On Newcastle-moor; two cases taken there to be destroyed by Mr. Bryson, town superintendent.
	Dec. 17....	See the case of distilling oil mentioned in the text.
1869.	June 30....	Near Carnarvon; two canisters of glycerine; 5 killed, and damage done.
1870.	Sept. 11....	Greenock; nitro-glycerine; 5 taken shelter in the unoccupied small tin can of the company on the wall, killed.
1871.	Aug. 11....	Prentice's Gun-cotton Manufactory (Suffolk); 20 killed, 70 injured; destruction of property, wilfully occasioned by the explosion at a certain stage of the process.
1872.	Aug. 1....	Experiments with gun-cotton in the Treasury; no general alarm.
1875.	May 27....	Chemical store, Washington; 5 killed, 17 wounded; house destroyed.
1877.	Dec. 19....	Great explosion of dynamite at the Gotthard Tunnel (Switzerland).
	Dec. 19....	A dynamite factory at Gerona.
1878.	May 10....	Part of freight on board Albatross while in Loch Foyle; 5 killed. The entire ship and cargo destroyed.
	May 17....	Dynamite at Nobel's factory, Faversham; 2 killed.
	July 3....	Dynamite at the Yarlside Mill, Faversham.
1879.	May 16....	At the Patent Cotton Gunpowder Works, Faversham; 1 killed.
	June....	Detonators at the Home-office; It appeared that 12,000 in number, were in the hands of the police, under an order for having been found impure and unregistered on board the Albatross. They were intended for use in the mines, and were found in copper tubes, charged with mercury. There was a report that this could not be a loss, and he recommended that they should be destroyed by being placed in diluted nitric acid. This was approved by the War Department chemist, who stated that small quantities of detonators in this manner, and he now expected that the loss was due to the mistake in the operation on too large a scale of the 12,000 detonators, the water at once, and they could have become the nitric acid was poured in, and the chemical excitement such as to cause the explosion of the mercury.
	Nov. 7....	At Templecombe (Dorset); exploded from contact with water.
1880.	March 5....	At Craig (near Montrose); 1 killed and 1 injured.
	April....	Tar-distilling works at Silverburn; several injured. (First explosion.)
	April 28....	Benzine at a druggist's in London; 1 killed and 8 injured.
	April 28....	Cork; the extensive premises of the chemists and oil merchants exploded.

4. *Dynamite* in a railway waggon, at Stratford, Ontario; 2 killed and others wounded.

5. *At Messrs. Hodgkinson's*, wholesale druggists, Aldersgate-street. Vapour from aniseed, heated by gas; several killed; great destruction of property.

*Dynamite* magazine of St. Gothard Railway (Faido); 18 killed and wounded. From 40,000 to 80,000 cartridges exploded.

*The ship, Sapphire* of Antwerp, in Philadelphia Docks; cargo exploded.

*At the Rannymede Engineering Works, Egham, Surrey.*—A group of buildings used by Mr. Postlethwaite for the construction of torpedo and other steam-launches. The establishment is in close proximity to the Thames, and is surrounded by waste land, upon a portion of which a Norwegian gentleman has been engaged in the composition of a new fulminate for the detonating caps of the torpedoes used in naval warfare. A cask of this new composition, which, when first mixed, looks very much like ale with yeast on the surface, had been left in a small temporary wooden building, situated about 50 yards from the works, in order that the material might get dried by evaporation; and the substance, heated by the sun, or fired by a flash of lightning, suddenly exploded, with a sound like a clap of thunder. The temporary shed and its contents were blown to atoms, and a piece of the debris slightly wounded a boy who was fishing 60 yards off on the river bank. Very fortunately, the men had left work.

leg. 7. *In the Laboratory, Government Arsenal, Bridesburg, Philadelphia*; 2 killed, 10 wounded.

leg. 13. *Benzine* in ship, *Hansa*, in Lubeck Harbour; 12 persons injured, and ship much burned.

leg. 13. *At Her Majesty's Theatre*; explosion from accident to lime-light.

*Experiments* were made in December, 1880, by the of the Royal Arsenal, Woolwich, in company with Mr. Her Majesty's Inspector of Mines, and Major Majendie, Artillery, the Inspector of Explosives, with the view of ascertaining, if possible, the cause of the accidental firing of blasting in mines and quarries. Serious consequences have resulted from the deterioration of these charges while idly driven into the borings, and many men have been killed from this cause. Great uncertainty exists as to the conditions which create or contribute to the premature ignition, and a day was devoted to experiments, in the hope of eliciting information on the subject, and perhaps avoiding the occurrence of such accidents in future. Charges of gunpowder are usually subjected to violent treatment of various kinds, but might meet with under most unfavourable circumstances, without exploding; but in no case did blows or pressure produce an explosion, however excessive the application.

This is a miscellaneous table, designed to show the circumstances under which explosives of various kinds have produced destructive work, and the results of the experiments made by the author; and new compounds are constantly being discovered. I am glad to see that experience is being made from time to time, in viewing the explosive force during the transference of the substances required in considerable quantities. Regarding explosions on board ship—a subject of the greatest danger—it is clear that more regulations than any heretofore in force are required.

### EXPLOSIONS IN COLLIERIES.

This is the most frequent, as well as one of the most destructive forms of explosion, is that of fire-damp in collieries. In certain districts of the kingdom, such events are of common occurrence, and the sacrifice of life is immense. In the discovery of the safety lamp, and by other means, has already lent remedial aid. It is to be hoped that it may yet accomplish much in a direction which I shall hereafter allude to.

I propose now to give a table of the most important of such explosions during the reign, drawing largely in the middle

portions upon the data contained in Mr. Neison's "Preliminary Report" on the rate of fatal and non-fatal accidents in and about mines and railways, 1880.

TABLE D.—EXPLOSIONS IN COAL MINES RESULTING IN THE DEATH OF FIVE PERSONS AND UPWARDS, 1838-80 (UNITED KINGDOM).

NOTE.—These resulted from Fire-damp, unless otherwise stated.

The result of the 156 collieries enumerated in this table, summarised as follows:—

No. of casualties.	No. of deaths resulting.	
Jan. .... 13	278	July ..
Feb. .... 18	580	Aug. ..
Mar. .... 20	531	Sept. ..
April .... 9	425	Oct. ..
May .... 7	81	Nov. ..
June .... 9	424	Dec. ..

The lightest month is, therefore, 3 number of casualties and the result together; July has one more casualty heavier mortality; April and July then September; January, August have a like number of casualties, 1 months the fatality has been much November is heavy; but the three months are February, March, and latter more especially so. Now on the state of the barometer and there a series of years should surely then upon the causes then in operation, indicate the means of future avoid action "Dust."

The most fatal year embraces appears to have been 1866—according great catastrophe at the "Oaks" (ley, where poor Jeffcock voluntarily life in a vain endeavour to afford 1880 is also a very heavy year 1868 and 1873 were each remarkable Lancashire; whilst 1877 stands out of coal-mining in Scotland with fatality. It is, indeed, noticeable how certain appear to become disturbed at times and then remain quiescent for years influences in any degree account for added a few casualties.

The inspection of collieries was 1850, by 13 and 14 Vict. c. 100. were introduced in 1855, by 18 and again in 1860 by 23 and 24 Vict. 1872, by 35 and 36 Vict. c. 76, the the preceding measures were amended, and boys were prohibited in collieries. In 1862, an Act was passed it incumbent upon colliery proprietors duplicate shafts.

Attention was, in 1879, directed Academy to a case of explosion of coal occurred in July of that year in one of Rochdale (Gard). The coal strata dislocated, and the carbonic acid gas fully in the neighbourhood, and through natural passages, seems to be later in certain parts with sufficient to explode with two loud detonations quantity of fine coal into the galleries were asphyxiated, and two others threw themselves in a swooning state and be hauled up. That no flame or explosions of fire-damp is proved of burns on the bodies of the victims blasting cartridges did not go off, as stances. The gas is thought to be sulphuric acid (produced through stratified mass of pyrites) dissolving

finding its way down to triassic limestone. One of M. Kuhlmann, lately, an alembic, about 90 centimètres diameter, used for daily some 6,000 to 7,000 kilog. of consulphuric acid, was exploded, the combs being shattered and thrown out, and of the fire-place, 20 to 30 mètres in directions. Fortunately a slight hissing lasted a few seconds previously, so that the men had time to escape a terrible fate. One of the explosion M. Kuhlmann supposes follows:—This platinum apparatus was used; some 30 to 40 kilogrammes of consulphuric acid had been left in it; on water had been admitted through the top and the whole had been gently heated for hours. It is known that mixing sulphuric acid with water produces a good deal of heat. In the present instance, combination is supposed to have taken place instantaneously at a high temperature, generating a large amount of steam. From data furnished by Fabre and others, it appears that 40 kilogrammes of sulphuric acid, with water, is capable of producing, at least, 18 to 20 cubic mètres of vapour, sufficient to explode a platinum vessel of 10 litres capacity, and only 2 to 3 mm. thickness. As the combination occurred at about 100° C., the force would be greater. M. Kuhlmann has exploded the explosion several times in laboratories, and he finds that it always produces great violence where the quantity of acid is at least ten equivalents for one of acid. The difficulty of mixing these two substances, which have a very great affinity, but of which one is so different that they may react for several hours one on the other without any consequent combination, the need of management is obvious.

Experiments are now being brought forward for series with the electric light; this does not seem to me, in the nature of the case, to be doing the position in which the men have their seams especially; but where it is a question of safety should result.

Now sitting a Royal Commission on coal mines, whose report will be of great interest.

#### DUST.

It is now known that dust was highly inflammable before it was at all suspected that it was so. An instance of its intense inflammability was particularly recorded in the case of a mill at Millville, Massachusetts. The men were lighting the gas in the carding-rooms, and fibre hanging to the gas-pipe in an instant the flames had spread over the room, and the building was destroyed. Later instances have been frequently observed. But, in truth, the cause of the destruction of the Tradeston mill, now, had already determined that coal-dust, combined with the atmosphere in certain proportions, is explosive. Why not, then, pulverised substances?

#### EXPLOSIONS ARISING FROM DUST OF VARIOUS DESCRIPTIONS.

Breunery (Mons. Alsop's), Burton-on-Trent.—A workman provided with an unprotected

light, shortly after the starting of some new works, on attempting to make an examination of the working of a leather band, was met, on the opening of the door leading into the casing, with an explosion sufficiently powerful to throw the band out of gear.

Another brewer has since stated that no less than three explosions had occurred on his premises. Hence the pulverised malt combs must be held to be explosive when mixed with the air, by the rapid movement of the machinery, or otherwise.

1877. Dec. 20....At a wholesale candy establishment (Mr. Greenfield's) in New York; two lives lost, and much property destroyed. The opinion of experts, after it was found that the boiler had not exploded, was that gas had accumulated in the flue connecting the boilers with the chimney; but subsequent events leave no doubt that it was occasioned by dust, evolved in the manufacturing the candy on the premises. The loss to the insurance offices was very large. (See August, 1879).

1879. ....An explosion occurred, which gave rise to the theory that coal-dust will explode under certain conditions. Mr. Morrison, of Newcastle, tried experiments with anthracite coal-dust. He found this would, under certain conditions, ignite in a safety lamp.

August....Another explosion in a French candy factory in New York.—A workman, while bearing a tray containing moulds of pulverised corn-starch in the drying-room, stumbled and fell; the falling threw a heavy cloud of finely-divided starch-dust against a red-hot furnace; an instant explosion resulted. It was found the moulds had become so dry, and so highly inflammable from constant use, that only a rude shake was needed to fill the air with explosive particles.

Nov. 7.....In Kansas City, at a cracker (biscuit) and candy factory; 7 killed, and much property destroyed; fire following explosion.

The facts here noticed gave rise to a new theory, viz., that explosions in coal mines might sometimes arise from coal-dust, instead of fire-damp; Mr. W. Galloway therefore commenced a series of experiments, and communicated the results to the Royal Society. He stated that a certain mixture of air and coal-dust, not inflammable at ordinary pressure and temperature, becomes so when 0.892 per cent. of fire-damp (by volume) or more is added. It then burns freely with a red, smoky flame. In a dry and dusty mine an explosion may, he said, extend itself to remote parts of the workings where fire-damp is quite unsuspected. The wetness or dryness of the workings he stated to depend on the temperature of the strata in which they are situated, for if the temperature of the mine is lower than the dew point of the air at the surface, the ventilating current will deposit moisture as it becomes cooled in passing through the workings; and if, on the other hand, the temperature of the mine is higher than the dew point at the surface, the ventilating current will absorb moisture and tend to produce a state of dryness. He then pointed out that the temperature of the strata in the coal measures of this country increases at the rate of about 1° Fahr. for every 60 ft. below the surface, and therefore the comparative wetness or dryness of a mine depends on its depth. He has found that his own observations gave these results—that mines shallower than 400 ft. are damp, and those deeper than 700 ft. are dry and dusty. Between the 400 ft. and 700 ft. there is a kind of debatable ground, in which wetness or dryness depends for the time being on the temperature of the air entering the mine at the surface. In all dry coal mines the coal-dust lying on the floor of the roadway rises in clouds and fills the air when it is disturbed by the passage of men,

horses, and wagons, and a sudden puff of air such as that produced by a local explosion of fire-damp, or by a shot blowing its tamping, must necessarily produce the same effect in a greater or less degree, according to its intensity. Although 0.892 per cent. of fire-damp will cause an explosion, it is probable that under compression in a confined space a less amount may have the same effect.

Mr. Galloway propounded the theory that some kinds of coal-dust may, perhaps, require less fire-damp than others to render their mixture with air inflammable, and suggested that still other kinds may form inflammable mixtures with pure air. On the other hand, he mentioned an experiment with the return air of a mine where he found that the air had to be black with dust before ignition occurred. He mentioned that it was a favourite theory that fire-damp suddenly bursting from strata would cause an explosion of wide extent, and that traces of it could afterwards be found in the charring of the timber used in the mine. This so-called appearance of charring was, he said, due to a coating of the coked coal-dust adhering superficially. The practical suggestion made was that roadways in mines should be kept well watered to lay the coal-dust. In the case of the Dinas explosion (of the 13th of January), he had found on his last visit before the explosion that the water-carts were not being used. The manner, he said, in which coal-dust operates in 'setting fire to coal and timber is probably as follows:—The air is travelling rapidly in one direction along a gallery, throwing a continuous shower of dust, small pieces of coal, &c., against all surfaces in its course; at the instant the flame traverses it the coal-dust is melted; it then assumes the properties of flaming pitch, adheres to the surfaces against which it is thrown, and rapidly accumulates until it forms a crust of a greater or less thickness, according to the length of time the air continues to travel in the same direction. If there is enough air it will continue to burn, but if not it is soon extinguished, and a covering of "coke" results, and there is the appearance vulgarly call "charring." This throws a new light upon the circumstances attending colliery explosions in certain cases, and one which we may be sure scientific men will follow up.

#### FIREWORKS, GUN CAPS, CARTRIDGES, ROCKETS, AND WAR MUNITIONS.

Fireworks, employed for amusement, as also the more serious munitions employed in warfare, and the manufacture of sporting cartridges, &c., have been, and still are, attended with great danger; although legislation has done something to insure greater safety. I propose here to record some of the more serious casualties resulting from these causes:—

TABLE F.—EXPLOSIONS ARISING IN THE MANUFACTURE OF FIREWORKS AND MUNITIONS FOR SPORTING AND WARFARE.

1715. Jan. 13 ...Firework maker, Thames-street, London. Fireworks were being made on a large scale, in preparation for the king's coming to St. Paul's. 37 barrels of powder on the premises. The house blew up, and the ruins spread into a large conflagration, consuming more than 100 buildings. It is recorded, as an historical incident, that a child in its cradle was blown to a neighbouring church, and its life

1768. July.....America.—At Hart of 22 young ge school-house 1 rejoicings that being received (by the British gunpowder in u in the lower ro boy, seeing som raked them to exploded the e ing into fragme three.  
Another explosion on the same o details.  
1842. March 1 ...D'Ernst's firework —all employed

1880. May 1 .....Anc

1880. Sept.

As early

of London passed an ordinance containing following:—

*vi. Iur.*—That no person whatever be henceforth ed, at any time, to make or cause to be made any bework, or to fire or cause to be fired any such, within the City or Liberties thereof, except as shall be thereunto appointed by H. M., or by authority under him."

ordinance on the same subject was promulgated in 1697.

—by 38 and 39 Vict., cap. 17—regulations enacted regarding firework manufactories and under this Act prohibitive measures taken. The manufacture can no longer be carried on in densely populated districts.

### FLOURING MILLS.

ten years ago, it would have seemed quite strange to introduce such a title amongst the causes of explosion; not that such may not have then occurred, but because science had not then recognised their possibility. It was, indeed, known that flour was inflammable, and highly so, but as it was stated, not that it was explosive. It was a scientific investigation which followed the explosion of the Tradeston Mills, near Glasgow, in 1872, that first determined the explosive properties of flour under certain conditions. I have no doubt of ascertaining the number of flour mills in the United Kingdom, but they can probably be counted by thousands. In Hungary, in 1872, there were 20,691 water, and 482 steam flour-mills; in 1876, 1,176; in the United States, in 1879, there were about 24,000 flouring mills. Anything that affects the safety of these may therefore be of great interest.

I proceed to furnish a brief list of the accidents which, in the light of 1872, may be regarded as having been destroyed by "explosion":—

#### LIST G.—EXPLOSIONS IN FLOURING-MILLS.

.....The "Stow Mills" at Mascouta, Illinois. They were grinding "middlings," i.e., flour of the middle quality, as distinguished from the finer or coarser samples. About three o'clock in the morning, the miller in charge went up to the chamber (a large box extending through several storeys), as he had often done before, "to jar the middlings down"—they having clogged. He carried a small oil-lamp, which he placed on a beam just behind and above his head. He then opened a slide, and thrust in a shovel, which started the flour down with a thump, raising a cloud of dust, when instantly, as if it had been coal-gas, it flashed, burning the miller's hair and beard, and filled the box with a sheet of flame, which spread with great rapidity, and burned the mill.

This incident drew attention to the circumstances attending the burning of a flour-mill at Dover, Kentucky, several years before. Here the floor of the flour-box gave way with the weight of a man, great dust was created, which, the instant it reached the furnace in the boiler-room, to which it was naturally drawn down, ignited with an explosive flash, and burned the mill.

50 .. Schmidt & Co.'s Mill, St. Louis. The light, or globe-lamp, was held near a bran spout, extending the height of the mill. The dust ignited with a flash, and burned the mill.

.....Bertchey's Mill, Milwaukee. The fire originated in a candle being held near a feed-spout reaching through the mill. The ignition was instantaneous—several parts of the mill appearing to be on fire at the same moment.

.....Tradeston Mills and Granaries, near Glasgow. Explosion, followed by fire. The circumstances seemed inexplicable, and the fire offices interested instructed Mr. W. J. Macquorn

Rankine, C.E., LL.D., F.R.S., and Mr. Stevenson Macadam, Ph.D., F.R.S.E., to investigate and report. The following embodies the substantial result of this inquiry:—

"We have made a searching investigation into all the circumstances connected with this disastrous affair, and having inspected the premises, examined all surviving witnesses, visited various other mills, and inquired, by the examination of witnesses and documents, into the list of other fires and explosions of a like nature, we have to report as follows:—

"1. That the primary cause of the fire and explosion was the accidental stoppage of the feed of one pair of stones engaged in the grinding of sharps, which led to the stones becoming highly heated and striking fire. 2. That the fire thus generated inflamed the finely divided dust which was diffused through the air in the exhaust-conduits, and then passed on to the exhaust-box. 3. That the sudden combustion of the dust diffused through the air would produce a very high temperature in the gaseous products of that combustion, and this would necessarily be accompanied by a great and sudden increase of pressure and bulk—constituting, in fact, an explosion. 4. That the first effects of this explosion would be to burst the exhaust-box, and allow of the diffusion of the dust and flame through the atmosphere of the whole mill. 5. That this communication of inflammable dust and flame throughout the atmosphere of the whole mill was the cause of the second explosion, by which the gable walls were blown out, the mill reduced to ruins, and the wood-work set on fire. 6. That the stores or granaries were set fire to partly by the flame and fire from the mill travelling along the gangways, and partly from the burning materials falling through the skylights. 7. That no explosive or other foreign material was used in the manufacture of the flour, and that we found the steam-boilers uninjured. 8. That we have not been able to trace blame on the part of the proprietors of the mill, or of any one in their employment, as every precaution known at the time was used."

Passing from the particular to the general, they say:—

"We have ascertained, both from the evidence of eye-witnesses, and from printed and published documents, that fire-explosions, similar in their cause and nature to that at Tradeston Mills, are accidents of ordinary occurrence in flour-mills, especially since the introduction of the apparatus called the 'exhaust.' This fact, however, is little known to the general public, or indeed to any one except those practically employed in working such mills, though it appears to be better known on the Continent than in Great Britain, being mentioned in French and German treatises on flour-mills, but not to our knowledge in the standard English books on that subject. . . . It requires some consideration to see the reason why such fire-explosions are not much more frequent than they have been."

1878. May 2.....Washburn Mills, Minneapolis, probably the largest flouring mills in the world (containing 41 run of stones), and 6 neighbouring mills—6 in all. The building wherein the explosion occurred contained two independent mills under one roof, and was 7½ stories high, grinding from 1½ to 2 million bushels of wheat per year. The night hands had just come when, at 7.20 p.m., the explosion occurred; the whole building was levelled with the ground, and the entire city suffered a shock as from an earthquake, nearly all the windows being broken, and large stones thrown into the air descended through their roofs. The conflagration of the ruins extended the fire to much other property, so that the entire loss was estimated at near upon £200,000.

Many theories were again started, as that the Minnesota wheat contained more sulphur than that from any other State; but the facts brought to light in the "Tradeston" investigation afforded an entire solution.

NOTE.—Mr. John B. Kehl, proprietor of the Glen Flouring Mills, Chipewa Falls, Wisconsin, has since forwarded an account of a small explosion which he personally witnessed in his own mill.

Science has here stepped in and afforded the required relief. By means of powerful magnets fixed in the hoppers, particles of iron which formerly got mixed with the grain from the wire binding of the sheaves are now intercepted; particles of dirt are otherwise disposed of; and by means of gauze wire screens the dust is kept from contact with the artificial lights employed.

#### GAS (COAL)

The use of coal-gas for illuminating and domestic purposes took its rise early in the present century. It is impossible to estimate the precise degree of danger to life and property which have resulted. Hundreds of gas explosions occur every year; but many of these are very slight, and the fire insurance offices cover the damage done to property insured. It has sometimes been suggested that science should devise a means of making coal-gas less offensive to the sense of smell. It is well that this has never been done, or the danger from its use would have been ten times increased. Seeing that the manufacture of gas for the purposes of our great towns is frequently carried on in thickly populated neighbourhoods, it is fortunate that no great catastrophe has occurred. I mark a few of the more prominent explosions:—

#### TABLE H.—GAS EXPLOSIONS OF SERIOUS MAGNITUDE.

1841. Dec. 18	Gas-holder at Dundee Gas-works; 2 persons killed, and much property in the neighbourhood damaged.
1862. Jan. 1	The new gas-holder at Chatham.
1866. Sept. 13	Explosion at Sheffield Mine-hall; 4 persons killed in endeavouring to escape from hall.
1868. Oct. 24	Gas-holder at works of London Gas Company, Nine Elms, 10 workmen killed, and great destruction of property.
1876. Aug.	On board ship <i>Atalanta</i> , Cardiff. The ship was loaded with 1,400 tons of steam coal, and the hatches were kept down, gas accumulated, and coming into contact with a lighted match, struck by the second mate, exploded, killing 4 men, and greatly damaging the ship. A Board of Trade inquiry was instituted. (See result at end of table.)
1878. Mar. 8	Gasoline Gas Machine exploded in Town-hall, Harrison, Ohio, much damage.
June 6	On board steamer, <i>Cryssolite</i> , in the Alexandra Dock, Newport (Monmouthshire); 4 killed and 7 wounded, side of ship blown out.
June 29	At Cardiff, on board <i>Cadocosa</i> , a steamer, loading with 2,300 tons of steam coal, for Aden. 4 men were loading, when one lowered a light that the others might see better, and explosion resulted.
Oct. 11	Extensive explosion at Linsay Cotton Mill, Blackburn, a great number of the work-people injured, and stock of cotton fired.
1879. Jan. 6	Three, more or less, serious gas explosions in different parts of London.
April 14	At Vigo, on board the British steamer, <i>Strozakath</i> , from Newport, for Havana, laden with coals.
May 20	At Cardiff, on board Genoese brig, <i>Sentia</i> , <i>Aspidia</i> , laden with small coal for Laphore.
June 6	At Sittingbourne Gas Works, doing considerable damage. It occurred in the "Governor-house," and was attributed to failure of apparatus.
1880. Jan. 9	At Plymouth, in a stove; considerable destruction.
April	An experimental military balloon, at Menden (France); attributed to the effect of the high external temperature on the gas in the balloon.
April 12	At St. Martin's Church, Bradley, near Wolverhampton; organ destroyed, stained glass windows broken, and fabric partly destroyed.
July 6	Tottenham-court-road, London, spacious newly-laid gas mains, filled by leakage from old mains, exploded, causing considerable damage to persons and property, tearing up the road, and continuing to explode every few hundred yards along Bayley-street, Rathbone-place, and Charlotte-street.

1880. July 15 . At Bilston (Staffordshire), on streets, the sewers having gas, followed by a second explosion. The road then dried of yards.

Aug. 9 . . . . . Remarkable explosion of a Ladgate-hill, the flame on pipes towards the main; was arrested at an early stage.

1881. Feb. 5 . . . . . At Sheffield; great damage to drapery establishment.

It is seen from the preceding table to shipping engaged in the carrying is very considerable. After the exp *Atalanta*, in 1876, a Board of Trade held, and a report issued, the conclu was as follows:—

"The Court is of opinion that a cargo description, so especially liable to gener be ventilated by tubes fore and aft r underside of the deck, but not exten surface of the cargo, and having suff above the deck to be out of the reach of revolving cowls so as to create a thoro air fore and aft above the cargo, by w accumulating gas would be continuo And in no case should a vessel load allowed to proceed to sea depending u only for ventilation."

#### GUNPOWDER.

This explosive compound has now for something over five c its influence upon the destinies of been very considerable—perhaps those resulting from any other sin save the printing-press. Its direct war against the human race, and even to a greater degree than co foreseen. Here I have only to re light of its accidental, and not of destructiveness; and so regarded, degree of minor importance. Yet the immediate subject of explosio still a prominent place.

The City of London, in its Fir 1667, enacted as follows:—

"xxvii. Item.—That no gunpowder the walls of the City (except as afores secure places as shall be allowed and Court of Aldermen."

The exception related to the st powder to be ready for the blowing, ings in case of fire, the Great Fire c been so stayed. That it was frequ in this manner at subsequent fires ground for believing. The poet "Travis, or the Art of Walking written in 1715, makes pointed re practice, which, while the houses we of wood, no doubt had advantages.

"Mark! the drum thunders; fire, ye ar Behold the ready match is lit with fir The nitrous store is laid; the smutty tr With running blast, awakes the barrel Flamen sudden wrap the walls; with so The shattered pds sink on the smoky g

That gunpowder is capable of b for useful purposes, is truly east-off evils it has produced. In its app purposes of blasting in metal and c led to many disasters. But in re

ring works, such as the removal of the down Cliff at Dover, 19th September, 1850; removal of dangerous portion of the Undercliff, Wight, a few years later; its more recent opening for navigation, Hell-gate, East New York—where another great operation, said, is still pending—it has been of real aid. Yet, on the other side—that of wanton destruction of property—there is a sadly dark blot, as witness a table given in a later portion of paper, "Wilful Damage."

# **EXPLOSIONS OF GUNPOWDER FROM EARLIEST TIMES DOWN TO PRESENT TIME IN VARIOUS PARTS OF THE WORLD; CAUSE BEING STATED WHERE PRACTICABLE.**

- ...Gunpowder magazine at Londonderry; great damage.
- ...Venice—fire at the arsenal; explosion followed, reducing city to ruins.
- ...Magazine at Gravelines; about 3,000 people killed.
- ...At Dublin, 218 barrels exploded, killing about 100 men.
- ...Athlone, Ireland, great storm; lightning struck castle, and exploded powder magazine.
- 10...At Bremen, by which about 1,000 houses were destroyed, and 40 persons killed.
- ...France—some mules employed to carry gunpowder to Niort, stopping near Pileri, in Poitiers, and being incommoded by flies, stamped upon a pavement of some flints, and thus ignited some grains which had dropped from the bags they were carrying. A terrific explosion followed, not only destroying the mules and their drivers, but throwing down houses, and committing other devastation.
- 1 } Three serious explosions at the Hounslow Mills.
- 1...The city of Worcester was greatly damaged by a gunpowder explosion.
- ...Goree nearly destroyed.
- ...Two mills blown up at Waltham.
- ...The Royal Mills at Faversham blown up.
- 3...Italy—powder magazine at Crema; the town ignited.
- ...An explosion at Ewell Mills destroyed property valued at £8,000.
- 1...Powder magazine at Brescia, caused by lightning; about 3,000 deaths.
- ...About the same date a magazine at Venice, by lightning; 400 killed.
- ...Faversham Powder Mills.
- 7...Hounslow Powder Mills.
- 1...At Moulsey; 3 men killed.
- ...Three mills blown up at Hounslow.
- ...At Chester, destroyed many spectators at a puppet-show, and greatly damaged many houses.
- ...At Chambery; 18 persons killed, and several houses destroyed.
- ...Abbeville nearly destroyed; 150 inhabitants perished, 100 houses destroyed.
- ...Trichinopoly blown up; 300 inhabitants lost their lives, 340,000 ball cartridges were destroyed, and the whole foundations shaken.
- 4...At Hounslow; 2 persons killed.
- 0...At Picardy.
- 5...Epsom Mills were blown up.
- 3...Vienna received great damage, and several lives were lost.
- ...Civita Vecchia nearly destroyed.
- 3...Malaga gunpowder magazine; lightning.
- ...Sumatra gunpowder magazine; lightning.
- 0...Benloven magazine and laboratory; lightning.
- ...Tangiers gunpowder magazine; lightning.
- 1...A magazine destroyed by fire at Corfu; 72,000 lbs. of powder and 600 bombshells blew up; 180 men killed.
- ...Faversham Powder Mills.
- ...Dartford Mills; 6 men killed; great destruction of property.
- ...Ewell Powder Mills.
- 3...At Lubin, in Poland, the axle-tree of a carriage conveying powder to the army took fire, and destroyed a great number of houses and some public buildings; about 90 persons were killed and wounded.
- 1...At Bayona, the chapel at the new castle was blown up, and 100 lives destroyed.
- ...The barracks at Youghall blown up.

- 1794. Sept. 3 ...Powder mills at Grenelle, near Paris, exploded; near 3,000 persons lost their lives, and all adjacent buildings were destroyed.
- Dec. 20 ...Landau had its arsenal blown up.
- Dec. 31 ...Dartford Mills; 11 men killed.
- 1798. Jan. 14 ...Hounslow Mills; 3 men killed; great destruction of property.
- Aug. 10 ...At Dartford; 4 persons killed.
- 1798. May 20 ...Battle Mills; 3 killed, and great destruction of property.
- 1799. Jan. 14 ...At Dartford; 3 persons killed.
- July 13 ...At a mill on Twickenham Common; 4 men killed.
- 1800. May 28 ...A powder magazine at Nantes blew up, destroying many persons and houses.
- 1801. Mar. 30 ...Battle Mills; 1 man killed.
- 1801. April 25 ...Waltham Mills; 9 men killed.
- 1802. Sept. 8 ...Faversham Mills; 6 men and 3 horses killed.
- 1803. June 15 ...At Dartford; 2 men killed.
- Oct. 1 ...Powder mill, Roslin, near Edinburgh; 2 killed.
- 1807. Jan. ...A vessel lying in the Rapenberg Canal, Leyden, blew up, and destroyed the best-built portion of this interesting city.
- June 28 ...Powder magazine at Luxembourg; lightning.
- Sept. 18 ...Faversham Mills; 6 men and 3 horses killed.
- 1808. Sept. 9 ...Powder magazine at Venice; lightning.
- 1810. Jan. 16 ...Faversham Mills; 5 men, a boy, and some horses killed.
- Sept. 2 ...Eisenbach; 3 French powder wagons blown up; 54 lives and escort, with 28 houses destroyed.
- Sept. 24 ...Dartford Mills; 2 men killed.
- 1811. Nov. 27 ...The Waltham Mills blown up; 7 men killed.
- 1812. July 4 ...At Hounslow; 2 men wounded.
- July 14 ...Roslin Mills, near Edinburgh, blown up; 2 men killed.
- 1813. Aug. 21 ...Two explosions at Hounslow Mills; 3 workmen killed.
- 1814. Sept. ...Battle Mills; 3 men killed.
- 1816. April 16 ...Toulouse Powder Mills; 16 killed, others wounded.
- 1817. Oct. 3 ...Faversham Mills; 3 men killed.
- 1818. Mar. 19 ...Powder Mills at Brandy-Wine, U.S.; 30 killed, many wounded.
- 1829. Nov. 28 ...Powder magazine at Navarino; lightning.
- 1837. Aug. 23 ...Powder-laden lighter off East Greenwich, causing considerable damage to persons and property.
- 1838. Oct. 8 ...Hall's mills, Faversham; 4 persons killed.
- 1840. June 6 ...Powder magazine at Bombay; lightning.
- ...Also, about same date, Dum Dum.
- 1843. April 13 ...Waltham Mills; 7 men killed, and buildings destroyed.
- April 22 ...Powder magazine at Puzaloni, Sicily; lightning.
- April 23 ...Powder magazine at Gaucin, Spain; lightning.
- 1845. March 8 ...Algiers; two magazines, killing 43 workmen, 10 artillerymen, and 31 pontonniers.
- 1850. Mar. 11 ...Three explosions at Hounslow Mills; 8 persons killed.
- Sept. 29 ...The *Donna Maria*, Portuguese frigate, blown up at Macao, when firing a salute in honour of the Prince Consort; 200 men and boys reported to have perished.
- Oct. 13 ...The *Abdul Medjid*, Turkish line of battle ship, blown up in Bosphorus; about 500 killed.
- May 1 ...Fleet of powder-laden boats at Benares, causing death of 420 persons on the spot, and injuring over 900 others.
- 1851. April 3 ...Powder magazine at Tremevar, Hungary.
- ...At Hounslow Mills; lightning.
- 1853. Aug. 17 ...Powder magazine at Gibraltar; 5 men killed, 1 injured.
- 1855. Nov. 6 ...Powder magazine, Rhodes; lightning; 300 lives, and 400 houses destroyed.
- Nov. 15 ...French magazine at the Crimea, containing large quantities of munitions of attack; which also exploded English magazine; 53 killed and many hundreds wounded.
- 1856. Mar. 7 ...Hatton Powder Mills, Hounslow; 3 lives lost; caused by sparks from lamp.
- Nov. 6 ...Powder magazine at Rhodes; lightning.
- 1857. Aug. 10 ...Powder magazine at Joudpore, Bombay; lightning; 1,000 killed.
- 1859. Mar. 30 ...Hounslow Mills blew up; loss of 7 lives.
- Aug. 6 ...Ballincolig Mills, near Cork, blew up; 5 persons killed. (See 1861.)
- 1860. Sept. 10 ...Melford Powder Works, Argyleshire; 6 men killed; 3 tons of powder.
- Dec. 1 ...In shop at Norwich; 2 persons killed, and much property destroyed.
- 1861. May 27 ...Waltham Mills blew up; 1 killed, and many others wounded.
- Oct. 24 ...Powder mills, Ballincolig, Cork; 5 persons killed.
- 1862. Sept. 9 ...Nancy Kuke Powder Mills, Cornwall; 6 women killed.
- 1864. Jan. 9 ...The *Lottie Seigh* exploded in the Mersey, at Liverpool, in consequence of fire on vessel, caused by oil cans igniting; great damage to property.
- Oct. 1 ...At Erith, Messrs. Hall's magazine, 100,000 lbs. of powder; 10 men killed, and property damaged for many miles round.

1864. Dec. 9.....Powder store at Buenos Ayres exploded, killing 160 soldiers.  
Dec. 24 ...A powder vessel exploded at Wilmington, U.S., without other damage.
1865. Mar. 29 ...Faversham Mills; 2 persons injured.  
April 11 ...Four or five barrels of powder exploded in a shop in Southwark.  
May 24 ...At Mobile, U.S.; about 300 persons killed.  
Oct. 25 ...Ewell Mills; 2 men killed.
1867. Dec. 28 ...Faversham Mills; 11 men killed, and much damage done; shock felt at Canterbury, 10 miles off.
1868. Dec. 21 ...Another at Faversham Mills; 5 killed, 4 injured.
1869. June 19 ...Hounslow Powder Mills; 4 persons killed.  
Sept. 25 ...Black Beck Mills, Windermere; 3 persons killed.  
Dec. 17 ...Hounslow Mills; 3 persons killed.
1870. Mar. 11 ...Kaimes' Powder Mill, Rothsay; 5 workmen killed, and serious injury to buildings.
1871. Feb. 5.....Powder wagon on railway between Bardoz and St. Nazaire; 60 persons killed, and about 100 others injured.  
Feb. 6.....Dunkirk Powder Magazine; about 60 lives lost; caused by careless use of lucifer matches.  
Mar. 2 ...Powder arsenal, Morpes; 20 soldiers killed.
1872. Feb. 5.....Hall's Powder Works, Faversham; 2 killed, 2 injured.  
May 23 ...Roslin Powder Mills, near Edinburgh; several killed.  
May 30 ...Powder magazine, Porthwain Lime Rocks, near Oswestry; 6 killed.  
Sept. 6 ...Hounslow Mills; 3 lives lost.
1874. Jan. 7.....Carthagena powder magazine.  
Oct. 2.....The barge *Tubury*, on the Regent's canal, laden with 4 tons of blasting powder and 6 barrels of petroleum. The latter, it was believed, ignited, and fired the powder. Exploded near North-lodge, Regent's park, killing 3 persons, and doing vast damage to property.  
Nov. 3 ...Hounslow Mills; 4 killed, 2 injured.
1875. July 16 ...Hounslow Mills; considerable destruction of property; no lives lost.  
Aug. 17 ...At Barcelona, the Spanish steamer *Express* was loading with war material, and exploded; 50 lives lost.
1876. April 22...In a railway tunnel at Cymner, near Heath; 13 excavators killed.  
July 1 ...Hounslow Mills; workmen had left premises.
1877. May 6.....Powder mill at Schulan, near Blankenese (Hamburg); effects very violent; 20 killed, and much property destroyed.  
July 12 ...Powder manufactory at Okta, near St. Petersburg; 6 killed, and many wounded; fire followed, and much damage was done to property.  
July 30 ...Floating magazine on Thames; 3 killed.  
Oct. 6 ...Powder factory at Yérgusehoff, Plojesti, Austria, with immense stores; 16 killed and many wounded.
1878. March 31...At Marsh Works Powder Factory; "green charge."  
Nov. 29 ...Powder mill, Elterwater, near Ambleside, Westmoreland; 3 killed, 1 injured. [I quote from official report hereon in note below.]
1879. Feb. 10 ...Chilworth Mills, near Guildford; 2 killed.  
Feb. 21 ...Messrs. Hill's Mills, Faversham; 1 killed, and immense destruction of property.  
March 1 ...At Dalry, Ayrshire; powder for mining purposes.
1880. Jan. 8.....On a gunsmith's premises, at Doncaster.  
April 7.....Halton Mills, Hounslow; no lives, but considerable damage.  
May 8.....At Rothwell Powder Factory, Geesthacht, near Hamburg; 4 killed.  
At Worsborough Powder Mills, near Barnsley; men not allowed in mill while machinery at work; considerable destruction of property.  
Dec. 11.....At Marsh Mills, Faversham; in the testing-house, which was closed; shock very violent.
1881. Mar. 19...At Blackbeck Powder Mills, High Furness; 2 loud explosions; 3 killed.

NOTE.—The report of Major Ford, R.A., one of H.M.'s Inspectors of Explosives, on the Elterwater explosion, 29th Nov., 1878, contained the following passage:—"One lesson, at any rate, may be learnt from this accident—namely, that active supervision in matters of detail of foremen in gunpowder factories cannot be dispensed with. Such a system as was found to be in force at this factory ought to be impossible. . . . Better supervision on the part of the manager would have insured the observance of the special rule, which was, as it appears, habitually disregarded. It also appears that, where access can be obtained to a factory during the absence of the men, it would certainly be advisable not to leave the keys of the powder buildings where anyone who has been employed about the place can obtain them. Lastly, the great value of trees as a screen to powder buildings is again forcibly illustrated. Large pieces of burning wood are very likely to be caught by tall trees, and even a small branch is sometimes sufficient to stop tiles and slates."

this country as an article of commerce £300,000.

It is seen that a considerable number of explosions enumerated in this table were lightning. I do not think it must from this fact that powder magazines, particular or peculiar attractions to fluid, although it may be thought that compounds there collected may delieve the real fact to be that the situ powder mills affords an entire solution problem. They are mostly located on near rivers, where there are few built electric fluid may be attracted by moisture towards their localities. Ice-houses a lightning in a like manner, and from the same cause; but on this point I some difference of opinion. It cannot that there is any other resemblance between mills and ice houses.

#### METAL MINES.

The metal mines of this country from the coal mines) suffer very fire-damp, and explosions consequently. In the 18 years, 1861-78, there have been 54 deaths from this cause in the 1 in Derbyshire district, 2 in the Yorkshire district, 18 in Northumberland district, 18 in North Shire, Cheshire, and Shropshire, Staffordshire and Worcestershire, 1 in Scotland district, and 11 in West Scotland district.

#### MINERAL OILS.

Another important element in the use of explosions during the present arises in the use of mineral oils, and its products. This oil came into use on account of its comparative safety after its discovery, in 1859-61, in the coal regions of Pennsylvania. It is inflammable at a very low temperature and much mischief has resulted in the use of it. There is now a Petroleum Association for the purposes of the public safety. The individual catastrophes counted by the hundred, and even by the larger ones traceable to explosions numerous; and yet probably nearly all the catastrophes laid to its charge have resulted in explosions.

TABLE J.—SERIOUS EXPLOSIONS RESULTING FROM MINERAL OILS.

1868. Dec. 13 ...Three Bridges Railway Station killed.  
1869. Oct. 28 ...Bordeaux Harbour; 16 vessels many others injured.
1871. July 18 ...Manufactory, near Rheims; at Oct. 4 ...Cheltenham. Triple explosion at Manor-street, King's-road.  
Oct. 16 ...Erith.—The brigantine *Bat* barrels of petroleum, 100 on board the *Tubury*. The explosion was occasioned by the vapour of petroleum on board. (See 1878.)
1878. July ...Petroleum factory at Lyons; 3 killed.  
1880. June 4 ...Terrific conflagration caused Thinsville, Penn.; £20,000 destroyed, and large portion of town destroyed.

NOTE.—Many great conflagrations have occurred at "Petrolia" and elsewhere, from the vapour acting upon the vapour.

The annual value of gunpowder exported from

keeping of petroleum is now regulated Parliament, enacted in 1862, 1868, and cetera. The supply of the oil has no indications of falling off in the West, but new sources of supply are found in Bohemia and elsewhere.

### STEAM BOILERS.

Let us come to notice the explosions of steam boilers. The gradual but now general use of steam into our locomotive applications into our manufacturing operations, in the present century, I have already said. Steam boilers may be divided into four classes:—1. Marine; 2. Manufacturing; 3. Locomotive; 4. Domestic. And in each class we need to be managed by those who understand their construction and requirements. The majority of casualties—and these have been many in the past, if they are not now, of alarming magnitude—arise from ignorance or negligence. I have endeavoured to frame an estimate of the steam boilers of each class in use in this country hitherto without success. The numbers are a very large aggregate. The evidence of the Select Parliamentary Committee, in 1870, bore into the causes of boiler explosions the result of the labours of a like committee in 1870 pointed to a belief that there were more than 100,000 steam boilers—exclusive of locomotive engines, steamships, and hot-house boilers—in the United Kingdom at that date. An estimate I had previously confirmed this view.

### THE MORE SERIOUS EXPLOSIONS OF STEAM BOILERS, IN THE VARIOUS CLASSES DURING THE PRESENT CENTURY:—

Marine boiler on board the *Victoria*, of Hull, on experimental trip from London to the North; 3 killed.  
Machine works of Messrs. Elice, Manchester; 6 killed and many injured; also much property destroyed.  
*Telegraph*, high-pressure steamer, at Helensburgh pier, N.B.  
Bolckow's Iron Works, Middlesboro; 4 killed, and 20 injured.  
Mr. Samuda's Works, Blackwall; 3 killed outright, and many wounded, some of whom subsequently died.  
*Crick* steam-boat, at Hungerford-bridge; 6 killed, and 12 seriously injured.  
Lambert Bottom Mills, Preston; 7 killed.  
Printing-office, Hogue-street, New York, causing destruction of entire building—six storeys; 90 killed.  
*Red Rover*, at Bristol; 6 passengers killed, and nearly all on board injured.  
French war-ship *Valmy*, blown up in Torbay; 20 killed.  
*Floer*, exploded while getting up steam in Glasgow Harbour.  
Marland's Cotton Factory, Stockport; 20 killed.  
Steam tug at Conham Ferry, near Bristol.  
*Times*, screw steamer, Dublin Harbour; 12 killed, 10 of whom were passengers.  
Williamson's Calico Factory, Rochdale; 10 killed. Inexperienced persons getting up steam.  
Walker's Ironworks, Newcastle; 6 killed and many injured.  
Upper Apaley Mill, Huddersfield; 8 killed, and many injured.  
*Black Eagle* steam-tug, in Cardiff Dock; 5 killed.  
Edward's Spinning Mills, Dundee; 19 killed, and 14 injured. Building destroyed.  
Portable steam-engine, at Levens, Agricultural Show; 5 killed and many injured.  
*Swan*, in Yarmouth Roads; 11 killed, and great loss of live stock, forming cargo.  
Furber's threshing machine in Langton (Yorks); 2 killed and 6 injured.

1862. April 15....Millfield Ironworks, Priestfield, Staffordshire; 28 killed and 10 injured. Three-fourths of the boiler, weighing about 8 tons, was thrown from 200 to 300 feet in the air, and in falling caused great destruction of property.  
Nov. 8.....Locomotive engine, "Perseus," in engine shed of Great Western Railway; 2 killed, and much damage.  
Dec. 3.....Midland Ironworks, Masbore' (Yorks); 9 killed, and many injured.  
1863. March 8....Moss End Ironworks, near Glasgow; great destruction of life and property.  
1864. Feb. 17....Aberaman Ironworks, South Wales, 13 killed, many injured.  
1865. June 7.....Brewery in Burton; 2 killed, 5 injured.  
1867. Dec. 29....The Greek war steamer, *Bubonia*, blown to pieces; some killed, and many injured.  
1868. Sept. 27....Moxley Steel and Ironworks, Wolverhampton; 11 killed, and many injured.  
Oct. 2.....Elecar Ironworks, Newcastle; several killed.  
1869. Feb. 21.....Austrian frigate, *Rudetzky*, blown up off Lima; 380 killed.  
June 9.....Bingley, near Bradford, boiler in manufacturing premises; killing 9 children at play on ground adjoining the works.  
Aug. 11.....Steam-tug, off Custom-house Quay, Thames; 3 killed.  
14.....Steamer *Cumberland*, Ohio River; 20 killed.  
Oct. ....Bramley's Iron Foundry, Accrington; 5 killed.  
Nov. 3.....The *Thistle*, at Sheerness; 10 killed.  
Dec. 2.....A screw steam-lighter; all on board killed.  
3.....Britannia Iron Works, Wolverhampton; 8 killed.  
1870. April 20....Locomotive at Warrington; 5 killed.  
May 28.....Cleugh-hall Iron Works, Staffordshire; 4 killed and 9 injured.  
1872. April 11....Steamer *Oceanus*, on Mississippi; 6 killed.  
1873. Nov. 22....Cameron's Engineering Works, Glasgow; 4 killed.  
1874. Mar. 2.....Alderman Thompson's Spinning Mills, Blackburn; 12 killed; 20 injured.  
1876. Mar. 28....Locomotive in ballast train, between Kilmarnock and Irvine; 4 killed, 9 injured.  
July 14.....On board H.M. iron-clad turret-ship *Thunderer*, one of the boilers; 38 killed, and many seriously injured.  
1878. April 8....On board steamer *Orion*, in River Schelde; 1 killed.  
27....Messrs. Strong's Ironworks, Dublin; 16 killed.  
1879. Mar. 19....Harthill pit, Lankithgowsire; 6 boilers said to have exploded simultaneously; 3 killed, with great destruction of property; chimney shaft, 100 ft. high, knocked down.  
May 13.....Walsall District Iron Works; 5 killed and some wounded.  
June 29....Steamer *Black Swan*, in Yarmouth Roads.  
Oct. 6.....Messrs. Balm and Pritchards, Halifax; 6 killed.  
1880. Jan. 27.....On board steam-ship *Jones Brothers*, of Newport, at Bilbao; 3 killed.  
Mar. ....Glasgow Iron Works; 25 killed, and many injured.  
May 15.....Birchill's-hall Iron Works, Walsall; 25 killed, and many seriously injured.  
29.....Boiler at Gunpowder Factory, Weteren, near Ghent; 7 killed.  
June 6....Vivian Copper Works, Swansea; one of the men blown into a tank of molten metal.  
July 20....On board the *St. Orwin*, at Gibraltar; 3 killed.  
Oct. 27....Balfron Iron Works, near Dunfermline; 1 killed.  
Nov. 20....New British Iron Company's Works, Acrefall, near Ruabon; 4 killed.  
1881. Jan. 19....Providence Mill, near Batley (Yorks.); 11 killed.

A noticeable feature in the foregoing table—which must be regarded as illustrative only—is the large proportion of boilers which have exploded at iron-works. One of two things seems certain, either that inferior boilers are too often used on such works, unequal to the pressure required, or that the jarring of the rolling-mill or the steam-hammer produces mischief to the boilers or their setting, and so deteriorates them more rapidly than elsewhere.

With regard to marine boilers, happily an explosion of these is now an increasingly rare occurrence. The very idea of such a catastrophe at sea is terrible to contemplate. The Board of Trade regulations as to inspection and working have been most efficacious.

As to the boilers employed in our great manu-

facturing industries, the advent of the Steam Boiler Inspection Association (in 1855\*), and still more that of the Steam Boiler Insurance Companies, the first of which was that founded in Manchester in 1858, with Mr. B. B. Longridge as its chief engineer. When I made the calculations upon which the rates of this company were based, I hardly foresaw to the full extent the benefit which would result, from periodical inspection, in the way of prevention of accidents. By the end of the year 1860 the company had received proposals for the insurance of 3,149 boilers. Other boiler insurance companies followed, notably the Midland Company at Wolverhampton (in 1862), with Mr. E. Binden Marten as its chief engineer. In collecting the data for the calculation of rates and estimation of risks, in connection with this company, I obtained a considerable insight into the boilers in use in the Staffordshire iron districts, and certainly formed an unfavourable opinion of many of these.

By the end of 1868 the number of boilers under protection of the different boiler insurance companies was found to be as follows:—

1. Boiler Insurance and Steam Power Company (1858) .....	10,900
2. Midland Steam Boiler Protection and Assurance Company (1862) .....	2,600
3. Association for Prevention of Steam Boiler Explosions (Manchester, 1855-64) .....	1,900
4. Nation Boiler Insurance Company, Limited (1864) .....	2,000
<b>Total.....</b>	<b>17,400</b>

An estimate was then made that in the United Kingdom during the preceding ten years there had been 495 boiler explosions, by which 786 persons had lost their lives, and a yet greater number had sustained serious injuries. The annual explosions were estimated at 50, causing 80 deaths. Out of 16,411 boilers insured by the Boiler Insurance Company only 15 had exploded, being less than one per 1,000. The number of inspections made by the officers of the above insurance company in 1868 was 65,440, showing an average of nearly four inspections per boiler per annum.

The value of periodical inspection of boilers cannot be over-rated; and the practice has been largely extended by the insurance companies. The inspectors of the Boiler Company (Manchester), made, in 1878, no less than 79,423 inspections, of which 67,208 were ordinary examinations; 1,215 were internal examinations; and 11,000 were thorough examinations—the last two involving stoppage of the works for the purpose. And their value is at once seen in the return of the various defects reported to the owners of the boilers examined, as follows:—

Corrosion of plates and angle iron ....	1,825
Fracture of plates and angle iron .....	443
Safety-valves out of order, or over-loaded .....	1,890
Pressure gauges out of order .....	744
Water gauges out of order, or fixed too low .....	360
Boilers damaged from over-heating, owing to accumulation of deposit .....	21

\* On 31st December, 1855, this association had 200 members owning 820 boilers; at the close of 1859, 696 owners, with 1,619 boilers; but immediately on the formation of the insurance company the business of this association fell off. In 1864 the association added on the business of insurance. A similar inspection association had been founded at Huddersfield in 1858.

Boilers damaged in consequence of deficiency of water .....

Total .....

—all trivial defects being omitted from this return.

While no complete returns have heretofore been kept of boiler explosions, the insurance companies engaged in the business have kept records of such explosions over a series of years; and admittedly incomplete, they are still interesting and valuable, as far as they go. The following Table, going back more than half a century, shows the progress of boiler insurance, as commenced, has been compiled by Mr. E. B. Marten, and kindly placed at my disposal, with many other facts—which I cannot now use—for the purpose of the present paper.

TABLE L.—SHOWING APPROXIMATELY THE NUMBER OF STEAM-BOILER EXPLOSIONS IN THE UNITED KINGDOM, AND THE LOSS OF LIFE AND INJURY THEREIN, DURING THE PERIOD 1800—80.

Year	No.	Killed	Injured	Total
Unknown	1	0	0	0
1800—1809	1	3	5	8
1810—1814	5	10	5	20
1815—1820	7	42	23	62
1821—1825	3	8	0	8
1826	1	0	16	16

1880	1,536	2,293	2,297	6,126

tutions in the annual number of explosions somewhat considerable, but this may be the imperfection of the records; yet it has been more influenced by the state of war in the last two decades. This is a very striking degree in a comparison of 1864-7; and in a less striking degree in comparison with later years.

Number of boilers insured, and, therefore, action, in the United Kingdom, is from 40,000 to 50,000. The actual explosions during the last 19 years, as Mr. Marten, up to end of 1880, is 1,047 average of just over 55 per annum; and, in worse, giving a mortality of killed, 2,026—total, 3,350. Of the property destroyed by explosions, no record seems to have been taken, but taking the boilers as being of the 100 each at the time of the explosion—mainly an under-estimate—we have an amount of £104,700, and this is not including fittings, and to say nothing of by stoppage of works. Assuming that loss all round is £500 in respect to each explosion, we thus have an annual loss of say nothing of the loss of life; but I think we shall be told to-night that this is an under-estimate.

Mr. Longridge, of the Engine-boilers' Liability Insurance Company, has kindly sent me the following which, from a mechanical point of view, is of much interest, and some value:—

THE NUMBERS OF DIFFERENT KINDS WHICH HAVE EXPLODED DURING THE LAST AND THE CAUSES OF THE EXPLOSIONS, UNDER THE FOLLOWING HEADS, VIZ.:—

1. Defect of design, workmanship, or material.  
2. Defects arising in course of use.  
3. Negligence or carelessness of attendants.  
4. Causes extraneous or not ascertained.

CLASS.	A.	B.	C.	X.	Total.	Percentage.
Explosive	194	118	112	8	357	34.1
Agri-	106	82	67	7	242	23.1
Marine	82	44	31	16	123	11.7
Domestic	16	26	21	8	71	6.8
Acc.	10	8	25	2	45	4.3
Other	19	9	16	—	44	4.2
Fire, &c.	4	1	37	—	42	4.1
Boilers	17	1	9	8	35	3.3
Other	10	9	14	1	34	3.2
Other	9	2	16	5	32	3.0
Other	—	—	—	25	25	2.4
Total	347	277	342	81	1,047	
Causes	38.14	26.47	32.66	7.73		

NOTE.—The above particulars are summarised from the statistics published by Mr. E. B. Marten, of the Insurance Company.

Now, the actual cause of the explosion is not satisfactorily ascertained. But another practical interest may be applied, viz., if the works wherein the explosion occurred employed. I will take two years by the way:—

1864.		
Works.	No. of Explosions.	No. of Killed.
Iron works and foundries	9	20
Coal and other mines	9	10
Locomotive	6	7
Agricultural engine	1	2
Steamboat	2	3
Corn mill	2	6
Saw mill	2	1
Flax mill	1	1
Silk mill	1	1
Blowworks	1	7
Chemical works	1	0
Cement works, flint mill, brickyard	3	0
House	3	8
Boilers for other purposes	2	0
	48	74
1878.		
Iron works	9	20
Collieries and mines	9	10
Steam vessels	7	7
Kitchens	7	2
Railways (Locomotive)	4	0
Farms	3	1
Cotton mills	2	0
Flour mills	2	0
Flax mill	1	4
Woolen mill	1	3
Saw mill	1	1
Distillery	1	1
Paper mill	1	0
Waterworks	1	0
Chemical works	1	0
Brick works	1	0
Stone quarry	1	0
Picture frame works	1	0
	52	48

Iron works and mines in both years assert a most unsatisfactory monopoly. Steam vessels and locomotives are high, as also domestic or kitchen boilers. In 1864 there were no cotton mill boilers, in 1878 two.

In the matter of locomotive engines, great care in the construction and working have rendered explosions of very rare occurrence.

Domestic boilers in kitchen ranges are mostly under the control of those who have no mechanical knowledge, and too often but very limited powers of observation, and casualties are, therefore, to be expected. Mr. Samuel B. Goslin (a member of this Society) has published a useful little tract, "A Review of the Facts and Records in connection with Kitchen Boiler Explosions and Hot-water Boiler Explosions of 1881, with some Remarks upon their Prevention, and the Remedies."

There have been, from time to time, projects put forward for a Government inspection of steam boilers. This I conceive to be quite unnecessary, except in the case of marine boilers. The insurance companies do the work far more effectively and economically than it can be accomplished by any Government department. But in this connection, I may say I am glad to see before Parliament notice of a measure introduced by Mr. Hugh Mason, for enforcing better provisions regarding inquiries into cases of actual explosion. This is much needed. His Bill provides that, on the occurrence of an explo-

sion, notice of the various circumstances attending it should be sent within 24 hours to the Board of Trade by the owner or user. The maximum penalty for not complying with this direction is fixed at £20. The Board of Trade is thereupon authorised to appoint an engineer to make a preliminary inquiry; then, if it be deemed expedient, to have a formal investigation held by a Court consisting of two practical engineers and one competent lawyer, for the purposes of its investigations, the Court would have the powers of a Court of Summary Jurisdiction. Those who conduct these preliminary inquiries or formal investigations, are directed to report on the causes of the explosion and the circumstances attending it; and these reports are to be published by the Board. The Bill excludes from the scope of its operations all boilers used exclusively for domestic purposes, and those used in her Majesty's service, or on board steamships having certificates from the Board of Trade.

#### BOILER INSURANCE IN UNITED STATES.

In the United States, much attention is being paid to the subject of steam boiler explosions. Mr. J. M. Allen, the able president of the Hartford Steam Boiler Inspection and Insurance Company (established 1866), has founded, in the interest of that company, a publication, called the *Locomotive*, wherein all that relates to the subject is freely and fully discussed, and records of explosions are published. From its columns is prepared the following, otherwise almost incredible figures:—

CLASSIFICATION OF EXPLOSIONS WHICH HAVE BEEN PUBLISHED IN THE "LOCOMOTIVE" AS HAVING OCCURRED BETWEEN OCTOBER 1, 1867, AND JANUARY 1, 1880.

KIND OF WORK.	Number of Boilers Exploded.	Number of Persons Killed.	Number of Persons Injured.
1. Saw, planing, and wood-working mills	281	497	576
2. Steamboats, tugs, yachts, and steam barges	186	350	516
3. Railroad locomotives	165	240	236
4. Iron-works, furnaces, foundries, and machine shops	92	137	324
5. Paper, flouring, and grist mills, bleacheries, and print-works	52	98	132
6. Portable hoisting, threshing, and pile-drivers	68	125	137
7. Cotton, woollen, flax, and other fabric mills	55	72	131
8. Mines, quarries, oil-mills, and refineries	44	73	76
9. Heating and domestic boilers	29	10	33
10. Chemical, rendering, and slaughtering works	27	43	32
11. Distilleries, breweries, and sugar refineries	25	19	34
Miscellaneous—52 kinds not specified above	217	201	98
	1,299	2,506	2,612

In 1864, an Act was passed in the Pennsylvania Legislature, authorising the Mayor of Philadelphia to appoint a proper officer to inspect the steam-boilers in that city, without whose certificate no steam-engine or boiler should be put into use, with full power to enter upon premises, and order removal of buildings necessary for effective inspection. The deaths from explosions in the

United States, during the year 1870, was as being 290.

#### WILFUL DAMAGE.—DIABOLICAL EX

An examination of my records show are, unfortunately, sufficient of the Class," i.e., wilful damage to life or justify a special tabular enumeration. sary to state here, as in the other tabular enumeration is not to be regarded as complete. It does not seem that an explosion has originated in the present century, but its recent development rapid and daring.

TABLE M.—EXPLOSIONS WILFULLY CAUSED DAMAGE TO LIFE OR PROPERTY

1845. . . . .	"When the Swedish fleet, which up in winter quarters at W paring to leave that port i 1845, certain ambiguous i Pomeranian, called Hans Gr so much under suspicion th searched, and in it were t packed with all sorts of expl mable materials, in the m been concealed clockwork i 12 hours after being set co an explosion. 1879. March	...At Czeow; the explosion of of the police-office.

- ...Blowing up of Winter Palace in St. Petersburg; many killed and injured; much property damaged.
- ...In the Casino, at Monte Carlo, a tin box, filled with gunpowder, had been placed under a large clock, which was exploded with a slow match; many injured.
- ...Explosive packages were placed on the main line of London and North-Western Railway, near Bushey, in view, it was supposed, of wrecking the Irish mail.
- ...Explosive substance introduced into coal supply of engine attached to night mail to Liverpool and Manchester; much damage done to engine, but the train escaped destruction.
- ...At a ball at Schwarzenburg, Saxony, a young man entered, having what appeared to be a cigar in his mouth. He went to the chandelier as if to light it, and a terrible explosion ensued. The lights were extinguished, the walls partly gave way, dancers of both sexes were covered with blood, and the young man was blown to pieces. He had resolved on committing suicide, and had adopted a dynamite cartridge for that purpose."—*Times*, Dec 9, 1880.
- ...Explosion at Marsh Powder Mills, Faversham, caused wilfully; £500 reward offered.
- ...The Emperor of Russia assassinated in St. Petersburg, by means of Orsini bombs:—"A French sailing vessel, the *Cordale*, which has put in at Dunkirk to revictual, left Pampeluna on New Year's-eve, with a cargo of Orsini bombs, destined for St. Petersburg. Strees of weather obliged her to take refuge at Bordeaux, and on her continuing the voyage, several of the bombs exploded, killing three of the crew. After a month's detention at Havre, the authorities allowed her to proceed, being satisfied that there was no further danger, but on reaching Dunkirk, the captain learned what had happened at St. Petersburg, whereupon he reported to the Russian Consul the nature of his cargo, and has suspended his voyage pending an investigation."—*Times*, March 21, 1881.
- Attempt to blow up the Egyptian-hall of Mansion House, London, with gunpowder.

machines have long been used in war-irist introduced by an Italian engineer, siege of Antwerp, 1584-5.

#### CONCLUDING OBSERVATIONS.

ct—which, I believe, has not been eated of as a whole—has grown: upon This paper can still only be regarded for further inquiry and observation. ers' Liability Act, 1880, will force the of the great risks arising from boiler ore fully upon employers than here- l, in truth, there need be small pity ho shall be found defaulters in this e means of safety are ready at hand. e companies have their agencies in the kingdom. A proposal to insure, ures inspection, and hence almost ivery of defects. Insurance here, as r cases, affords nearly all the remedy ake it, that no insurance association, r an employer under the provisions of uld think of enteriug upon a risk mployer had not insured his boiler. be, *prima facie*, an act of negligence. ide an effort to estimate the annual erty resulting from explosions of in this country; but the data avail- urther insufficient for the purpose. ife is very sad, but can be approxi- gh the aid of the returns with which y dealt. I do not believe those re- et complete.

mexion with colliery explosions, per- e greatest loss is sustained. In 1865,

there were as many as 3,268 collieries in the United Kingdom, employing 307,542 miners, who produced 98,150,587 tons of coal, valued at the pit's mouth at £24,537,646. In 1873, the number of collieries had increased to 3,527, and all the other figures in a like degree. There is now a much larger number at work. In one of the most dangerous districts of the kingdom, there had occurred, in 16 years, accidents by explosion, costing £56,914; these ranged from £200 to £25,000 each. This—supposing all collieries to be equally fiery, which is happily not the case—would give £910,624 as the loss sustained throughout the United Kingdom in 16 years, being £28,457 per annum. The total value of 3,180 collieries at another period was estimated at £70,000,000, giving an average of £22,000 per colliery; hence, the rate of premium to be paid for insurance against colliery explosions might be nearly calculated; but there are other difficulties in the way. Besides, we are not here to discuss insurance, except in so far as it may aid in the reduction of the number of accidents. In some Continental countries, as, for instance, Austria, insurance against explosions of all kinds is very general. I think it may, with advantage, be made so here.

In furnishing the details herein contained, my object has been the prevention, i.e., the lessening the number of explosions of all kinds. The details of the occurrences and their causes are designed as a means to this end. To know the cause of an evil is sometimes regarded as half the remedy. I sincerely trust it may prove so in this instance. Science may, in this matter, help forward the cause of humanity. I look to those now present, or who may read this paper in the *Journal* of the Society, to do their share in the following up the considerations I have raised, and in throwing light upon points which I may have overlooked.

NOTE.—I have not attempted on this occasion to deal with those great convulsions of nature—physical explosions—usually designated earthquakes. I am treating of these in connection with my inquiry into plagues and pestilences. It will be observed that I have almost in every instance, given the month and day of the explosions here recorded. This is done very much in view of meteorological investigation hereafter.

#### DISCUSSION.

Mr. Christopher Cooke said he remembered an explosion at a firework manufactory, in the Westminster-bridge-road, by which several lives were lost. Explosions of gas he thought were generally due to ignorance and carelessness, through people going to look for an escape of gas with a lighted candle. He believed the researches of Scott and Galloway showed that there was a connection between the atmospheric pressure and explosions in coal mines.

Mr. Longridge said he was only specially interested in one out of the many cases of explosions which had been treated of, viz., boilers, and he had come rather to listen than to speak, hoping to get some further statistics on the subject, as he knew that Mr. Walford had a great faculty for obtaining and utilising information of that character. He had been more occupied with the inspection of boilers than inquiring into the causes of explosion, but he quite agreed with Mr. Walford that most of these explosions could be prevented by efficient inspection. He

was, however, opposed to compulsory inspection, because it would be a great obstacle to progress. They saw what had been done in the way of compulsory inspection of factories, mines, and steamers, and he did not think the results were sufficiently encouraging to warrant extending the system. The inspection of steam-boilers was being carried out at present by the insurance companies, and he thought compulsion would be a mistake. It would necessitate the setting up of a standard, to which every boiler must conform or be condemned, whilst it would be impossible to fix any standard which would be applicable to all boilers, working as they did under so many different conditions. Again, if you had compulsory inspection, you relieved the boiler owner from an immense amount of responsibility; he would be compelled to adopt the recommendations of the inspector, and would then claim to be relieved of that responsibility which every boiler owner ought to be under. The course proposed in Mr. Mason's Bill was far preferable, and he must say, from some experience, that the inquiries as at present conducted were almost ludicrous. The absurd questions put by the coroner, or by the lawyers, led to an immense waste of time; whereas, if there were a couple of men who understood the subject, the inquiry would be got through much quicker, and a more satisfactory result would be arrived at. Under the present system the almost invariable result was a verdict of accidental death, though in one or two cases there had been a verdict of manslaughter. In one case in Scotland, where a man was tried for manslaughter, the jury returned a verdict of "not proven." If they could get the causes determined, explosions might be prevented in future. They were generally said to be accidents, but in the majority of cases that was simply untrue.

Mr. Proude said he had seen a little of the use of steam in the colonies and the East, both afloat and ashore, and on one occasion witnessed an explosion by which more persons were hurried into eternity than he saw at present before him, and many more were seriously injured. At that time he was organising a large steamship company on the coast of China and Japan, and, from his experience of what were commonly called the black squad, he only wondered there were not more accidents than there were. They were, he believed, in many cases, due to the gross carelessness, and even incompetence, of the men in charge of the boilers. He could not speak of the effect of steam hammers on boilers, but he could say, from personal experience, that boilers used in connection with stampers for crushing quartz, and brought close to the stampers, as they often were to avoid loss of steam, were seriously affected by the constant vibration. He would urge the necessity of encouraging a more intelligent class of young men to come forward, and make themselves competent to take charge of steam-boilers, and he did not think a little higher rate of pay would be a very heavy tax on the owners of steam machinery. In Yokohama and Jeddo he had seen many hundreds of men who applied for situations; but really steady, competent, sober men were in a lamentable minority.

Mr. F. J. Bramwell, F.R.S., said this most interesting paper touched on so many subjects that it was impossible to discuss it as a whole, but there were one or two matters alluded to which had come within his cognisance, and on which he might say a word or two. He had had a good deal to do with flour mills, and with the introduction of the blast and exhaust into English mills, which the late Mr. Rankine seemed to think responsible for the explosions from flour dust. Now he observed that both the great explosions in America and in Glasgow occurred when they were grinding, not wheat, but what was called in America and in England, middlings, and in Glasgow was called sharps. That meant regrinding a portion of the meal which had been taken out in the operation of

dressing, and had to be further ground and re-dressed. The material arising from this re-grinding would be much drier than if it were the product of the wheat itself; indeed, in the United Kingdom, especially, when grinding home-grown wheat, difficulty was not to prevent the exhaust from being too dry, but, on account of the excessive moisture, to prevent their contents fermenting and coming offensive. In the United States there was a greater chance of the conditions favourable to explosion occurring, both because the wheat was drier, because it was the habit, when he was there years ago, to run the mills at a much greater rate than English millers could afford (afford because the rate was accompanied by a bad yield), and thus the heat generated would be much higher than in this country, where grinding was carried on more slowly.

It would be easily understood how, when there were circumstances favouring the production of dust, which was diffused through the atmosphere, it was very possible for an explosion to occur. The cause of gas explosions was, no doubt, as they would go, as had been said, to look for an extinguished candle, which they generally held up to their heads; but after all, he did not think that had been an additional source of danger. It was true that tallow candles and whale oil did not explode, but more accidents occurred from sparks falling from a smuffed candle, from candles falling out of holders, from lamps upsetting, and things of that kind, arising from gas, the flame of which was put in a position where it could do no harm. In respect to explosions of gas works themselves, he had been some few cases, but very few, and he did not agree that the presence of gas works in a large population was a source of danger. It might be found that the explosion of gas-holders had occurred when they were in use, but when they were under repair, imperfectly emptied, and the men suffered to enter them, and thus an explosive mixture was formed. He remembered one instance at Newcastle where a gas-holder which was under repair had not been properly emptied, and a red-hot rivet being put in, the mixture exploded. He did not see that there was the slightest chance of an explosion while the mixture was going on and the gas-holder was full. At Goswell-street station of the Chartered Company, 16 years ago, a girder fell upon the gas-holder, broke it, and a neighbouring flame set fire to the gas, and the whole gas in the holder came right out without an explosion; it was an enormous gas bonfire. He was glad to find that there was a steady decrease in the number of boiler explosions, which was doubly encouraging, as the number must be largely on the increase. References had been made to the frequency of explosions in iron works, and it was suggested that this might arise from the being jarred by the action of the machinery. He much doubted if that were so, and such a cause was not needed to account for the frequency of explosions in these works, as there were other reasons which, in his judgment, were quite sufficient. In iron works often the waste heat from as many as four furnaces directed against the outer shells of boilers of very large diameter, a construction adopted when the pressure of steam was about 5 or 6 lbs. to the inch, a construction that had been continued when the pressure had risen to 40 or 50 lbs. The furnaces were of various causes, not all working at the same time, so that sometimes one portion of the boiler was heated and sometimes another, and thus it was exposed to a succession of injurious strains which did not occur under ordinary circumstances of boiler use. The plates were not of the most durable description, and strains gradually produced cracks, and the boiler was then it was called, and the very act of calling it so was destruction, and, finally, it exploded.

being situated in the centre of three or four furnaces, each of which two men worked, and, generally speaking, close to other boilers and furnaces of similar construction, the result was generally very destructive; bricks were hurled in all directions, and much damage ensued. In late years, however, the matter had been much better understood; and now it was usual for the heat from the furnace only to operate on the boiler, and the boiler instead of being surrounded by brickwork, was overhead, and covered with a non-conducting material; the heat drew through one or two internal flues; it was fairly treated as regards expansion and contraction; it was in full view for inspection, and even when an explosion did occur, it was not likely to do so much damage. It had been proposed, as a preventive of explosions, that the use of waste heat from the furnaces should be discontinued, but having regard to the frightful cost of fuel, there was by Belgian manufacturers, which required a great many of the wrought-iron joists used in buildings being now imported, instead of being made in England, it would be impossible for English manufacturers to hold their ground at all, if the great saving arising from the utilisation of this waste heat were taken away. He must dissent from the arguments which had been given to the Board of Trade in connection with regard to steamboats, which he thought had done a great deal of harm. We were getting into the condition which Mr. Longbridge pointed out would be the result of the introduction of compulsory inspection generally. If the Board of Regulations with regard to marine boilers were applied to locomotives, the result in round figures would be that the pressure used in locomotive boilers, which very rarely exploded, would have to be reduced to 10 lbs., and the result would be an enormous increase in the consumption of coal. He would here repeat what he said to the Boiler Explosion Committee in 1871, when it was proposed to introduce legislation which would be destructive to mechanical improvement in this country. He then referred to statistics which had been published to-night. In a paper read at the meeting of the Institution of Mechanical Engineers at Nottingham in 1871, it was stated that there were 55 explosions per annum causing 80 deaths, of which, on the average, 13½ from the negligence of the attendant—which no doubt would have prevented—and 3½ from kitchen accidents. Thus there were 17 out of the 55 which inspection could not prevent, leaving 38 which might have been prevented by the most perfect inspection. It also appeared that when inspection took place, one boiler in 100 exploded (now, it appeared the proportion was one in 2,000) as against one in 2,000 without inspection, so that inspection only saved 55 per cent. It therefore appeared that, that inspection as then practised would have saved 46 lives out of 80. Taking the number of boilers, as nearly as could be ascertained, 800, excluding railways, and making the best possible of the consumption per horse-power, it appeared that if anything were done which would save the consumption (or would prevent a saving) of coal per indicated horse-power per hour, it would involve the consumption of four million tons of coal per year. Now, looking at the returns of the inspectors, taking one year with another, it appeared there were ten violent deaths for every million tons of coal. If, therefore, a measure were passed which would have the effect of stopping the improvement of the boiler, and lead to a want of economy of 1 lb. of coal per horse-power per hour, you might save 46 lives by not exploding; but you would not only be wasting coal, but would be wasting 40 lives in extracting it. As he pointed out to the committee, you might say anything too dear, even human life, especially when you bought it with other human life. He was of the opinion that Mr. Walford came to the conclusion that compulsory inspection was not desirable, and Mr. Longbridge had very forcibly pointed out some objections

to it. However unnecessary the orders of the inspector, the owner would be practically compelled to obey them, and having done so, he would cease to be responsible. He might give an instance of how this would work. Many present were acquainted with the system of heating by hot water carried out by Mr. Perkins. Many years ago Mr. Perkins's father employed that mode for heating boilers; he applied the fire to hot-water pipes, which circulated within the boiler, and the boiler itself never saw the fire at all. A boiler thus constructed had been working 28 or 38 years (he forgot which) at the warehouse of a well-known furniture manufacturer in Tottenham-court-road. He had his boiler inspected by some boiler insurance company, and the order was given that the boiler ought to be discontinued, because it was so many years old. The question was put, "What is the matter with it?" and they could not find anything the matter with it, but still, it was so many years old. The owner felt compelled to have it replaced by a new one. He applied to Mr. Perkins for a new one of the same kind, when Mr. Perkins said there was no need to replace it, as there was nothing the matter with it; and, at any rate, before it was taken out, he should like to see if he could burst it. Accordingly, he (Mr. Bramwell) and several others went to see this boiler burst. It ordinarily worked at a pressure of about 50 lbs., and the pressure was got up to 200 lbs., when it leaked so much at all the seams, that it was impossible to get the pressure any higher. Yet this boiler had to be replaced on account of its age, when it was being safely worked at a pressure of one-fourth of that at which it leaked like a sieve, so that it would have been impossible to explode it. Another point which he brought before the committee, in connection with the economy of fuel, was this. In non-condensing engines especially, it was usual to turn the waste steam into the feed water so as to heat it, and thereby economise fuel, and this was very commonly done by simply blowing the waste steam into the water. This was forbidden by the engineer to a boiler insurance company, who said that it was liable to introduce grease into the water, and that this would act injuriously on the boiler. He pointed out to the committee of 1871 that if there were compulsory inspection, the great object of an inspector would be to say that there were no explosions in his district, and he would give orders which would ensure that result. Now the great bulk of the small engines in use throughout the country were of a very wasteful kind, being non-condensing engines, working at a comparatively low pressure, usually about 30 lbs. to 35 lbs. pressure above the atmosphere, a pressure which, being reduced by the throttle valve, would not show more than about 14 lbs. in the cylinder. Now the inspector going into a factory where 35 lbs. of steam was being used, would be very likely to say, "I will allow you to use the boiler, if you reduce the pressure to 10 lbs., which the owner would probably agree to, rather than go to the expense of a new boiler, and the result would be the consumption of so many tons extra of coal per year. He had been very much pleased with the lucid statement of Mr. Longbridge, whose prejudices certainly, if he had any, must have been in favour of inspection. No doubt it was very undesirable that anybody should be killed by avoidable accidents; and when explosions did occur, they were very startling and horrible; but before doing anything which would interfere with the progress of engineering improvement, on which the prosperity of the country depended, it would be well to stop the unnecessary loss of life in other directions. At the present time, the deaths from street accidents in London alone were from five to seven a week, or three or four times the number which were caused by boiler explosions throughout the whole country, and he thought attention should be given to such matters as these before anything was done which would interfere with mechanical improvements or with economy in fuel.

Mr. Gosling suggested that if a system of insuring

domestic boilers were instituted, many persons would take advantage of it, for many persons to whom he had spoken on the subject had expressed their desire to have their boilers inspected. He found that in many cases they had been in use for many years without being inspected. He often found, especially in country boilers, that the persons in charge of steam-boilers were lamentably ignorant and incompetent. One of the most important things to be looked to was to get a better class of men to attend to boilers.

The Chairman said there was so much matter in the paper that it was very difficult to deal with it except in the way of general approval, and some points on which he should have liked to touch, he hardly felt free to deal with. The question of accidents in mines was now in the hands of a Royal Commission, of which he was a member, which was carefully investigating the subject, and he hoped some fruitful results might ensue. He might point out, however, that the accidents in coal mines due to explosions, formidable as they were, bore but a small proportion to the accidents due to other causes, by which one or two lives only at a time were sacrificed. It would be a mistake to introduce anything like over-legislation in connection with any branch of the subject; and it should be borne in mind, as Mr. Bramwell had justly observed, that there were other important sources of casualties which equally required to be dealt with. Many accidents ascribed to explosions were not due to explosions at all, especially those in connection with petroleum. As had been said, explosions did occasionally occur in manufactories or stores of petroleum, but the accidents with petroleum were generally due to spilling, or overturning of lamps, not to an explosion in the lamps themselves. Again, in the case of chemical explosions, which embraced a large variety of accidents, many would hardly come properly under the description frequently given of them. In some instances they might be due to spontaneous action occurring amongst substances mingled or brought together, or they might be due to the secondary action of fire, which caused an explosion. In the case of the Gateshead explosion, although it was chiefly attributed to the action of steam, there were all the elements of a gigantic explosion of gunpowder present. There was an enormous store of nitrate of soda, which was only another name for saltpetre, besides large stores of sulphur, and of charcoal or carbonaceous matter, and although the explosion might be due to large volumes of water meeting with highly heated matter, yet those materials meeting in a highly heated state might develop suddenly large volumes of gas under high pressure, and thus contribute to the violent explosive effects produced. With regard to explosions due to dust, on which Mr. Bramwell had given interesting information, he had lately had occasion to look into this subject, and regretted that time and other circumstances did not admit of his giving the results of numerous experiments he had made in connection with the influence of dust on explosions in coal mines; but there was no doubt it was much greater than they had been disposed at one time to believe; and that serious and fearful as was the effect of fire-damp, in many instances coal-dust itself played a part quite as serious, if not more so. He concluded by proposing a vote of thanks to Mr. Walford.

The vote of thanks having been carried unanimously,

Mr. Walford briefly acknowledged the compliment, and said he trusted that the subject would, from time to time, receive that attention and elucidation which it deserved on the score of humanity. He thought there was a real reason why marine boilers should be placed under more stringent regulations than land boilers: as a ship at sea, in the event of a boiler explosion, presented a case of real disaster.

## MISCELLANEOUS.

### SANITATION AT THE GOVERNMENT OFFICE

Mr. Gorst asked in the House of Commons, day, 21st inst., for information respecting the alterations about to be made in the public office reply

Lord F. Cavendish said that nothing was so as to say how much works of this nature would be War-office was in a satisfactory condition, but almost the only public office that was so.

Sir E. Cross said that he had found when he the Home-office that he suffered much from headaches. The clerks refused to go to the new on account of their unsatisfactory condition, himself had almost resolved to take lodging in the neighbourhood and charge the Treasury with it. They could find no plan of the drains, and the were made in Whitehall-place before the junction the main drains could be found, and then the discovered 2 ft. of sewage matter. It was a must be thoroughly investigated, and remedied hazards and all costs. Unfortunately, it was sible to say what the cost would be.

Lord John Manners said that it was absolutely sary that these sanitary improvements should be out without delay. When the new great public were undertaken, the highest engineering skill employed to insure that the sanitary arrangements properly carried out.

Lord F. Cavendish said that, with the exception the War-office, nearly all the public offices, like of the other houses in the neighbourhood of were in an unsatisfactory condition. They, proposed a substantial vote, and intended to the worst of those offices, the Home-office. system of drainage was bad, but the fault with the architects. He might mention that of Works had laid down certain simple regulations prevent the recurrence of the evil.

### COPYRIGHT.

The Committee of the Jurisprudence Department the Social Science Association have been engaged preparation of a series of twenty-one heads, they deal with the whole question of copyright, following is an abstract of the heads which posed to incorporate in a Bill hereafter to be before Parliament:—

1. That registration of copyright in works classes published in the United Kingdom dramatic or musical works first performed in Kingdom though not published (but not in drawings, or sculpture, since there is nothing analogous to publication), should be compulsory.
2. That if owners of copyrights in paintings, or sculpture, should desire to register their rights, for the purpose of evidencing them otherwise, they should have power to do so.
3. That it is desirable that registration effected at a Government office, to be established and maintained for that purpose.
4. That in the case of books, photographs, engravings, or similar works, copyright should be an exclusive right of multiplying copies of the work protected.
5. That the term of copyright should be limited from the date of registration.
6. That in the case of paintings, drawings, sculpture, copyright should mean the exclusive right of multiplying copies of the design of the work protected.
7. That in the case of paintings, drawings,

term of copyright should be the life of the author and thirty years after his death.

at on the sale of a painting, drawing, or piece of sculpture, or when such work is executed on commission, the copyright in it should remain with the artist, in the absence of a written agreement to the contrary. That the purchaser or other owner of a painting or sculpture should be protected against replicas.

at the present law by which, in the case of a painting, drawing, or other collective work, the copyright shall belong to the producer of the collective work, a right of separate copyright reverts to the author after twenty-eight years, should be modified, three years being substituted for twenty-eight.

at the present law as to presentation of books to the British Museum and other libraries should be altered.

at in the case of British subjects copyright in a work should be passed should extend to all the dominions.

at aliens, wherever resident, should be entitled to copyright in paintings, drawings, and sculpture, if their works are introduced into the British dominions in order to sell them there; and to copyright in other classes.

a British author, who first publishes his work in the British dominions, or whose play or composition is first performed out of those dominions, should not be prevented thereby from exercising copyright in those dominions by subsequent publication or performance therein.

14, 15, relate to the power of search which is to be conferred; 16, 17, to the colonial question, 20, 21, to copyright in foreign books and

act of artistic copyright is one in which the Society has long been interested. In 1858, a resolution was appointed by the Society, with the late Sir Eastlake, President of the Royal Academy, to consider the subject, and the ultimate result of their labours was "an Act for amending the Copyright Act in works of the Fine Arts, and for preventing fraud in the production and sale of copies," which was passed in 1862. The Act of Lord John Manners' Copyright Bill, introduced in the *Journal*, vol. 27, p. 879.

## NOTES ON BOOKS.

**Art Buildings:** their construction, heating, ventilation, &c., with remarks on some of the points involved, and their application. By F. J. Es. London: B. T. Batsford.

For points out that while much is written about flowers, and fruits, it is somewhat difficult to obtain information respecting the proper construction and arrangements of buildings required for the cultivation of those plants, flowers, and fruits. He, therefore, intends to produce a volume in which an amateur could find just those constructional and horticultural points which are required by the horticulturist in which a gardener could find details of the province with which he should be acquainted. The various questions relating to growing in glass-houses, garden-frames, subsidiary buildings, the materials used in them, besides the materials used for heating, ventilation, and water supply, all dealt with in this volume, which contains many illustrations.

**of Great Britain:** a Text-Book of Agriculture adapted to the syllabus of the Science and Art

Department, South Kensington. By Hugh Clements, with an introduction by H. Kains-Jackson. London: Crosby Lockwood & Co., 1881.

This little book is a reprint of a series of articles contributed to the *Farmer*, and is intended by the author to form a text-book for the use of teachers and students of agricultural classes connected with the Science and Art Department, the elementary and advanced stages being dealt with as a whole. The chief subjects treated of in the different chapters are, soils, irrigation and drainage, farm buildings and implements, crops, constituents of food, stock, &c.

**Andrea Sansovino und seine Schule.** Für Künstler und Kunstfreunde, von Dr. Paul Schönfeld. Stuttgart: verlag der J. B. Metzler'schen Buchhandlung, 1881.

Dr. Schönfeld has here given a study of the works of Andrea Sansovino, the great sculptor and architect of the Italian Renaissance, and of those of the school which he formed around him, including Jacopo Sansovino, Alfonso Lombardo, Niccolò de' Pericoli, Francesco da Sangallo, Lionardo del Tasso, and other famous sculptors. In illustration of the essay there are added thirty permanent photographic plates of the chief works of these artists.

## GENERAL NOTES.

**Gas-lighted Buoys.**—Compressed gas for the illumination of buoys, according to the *Times*, is gradually coming into use. Ordinary coal-gas is not employed, but an oil-gas, manufactured upon Pintsch's system, which has been adopted by several railway companies for carriage lighting. The gas is produced by distilling the refuse of shale oil, the gaseous products being stored and used under pressure. The buoy is made of wrought iron, and is itself the receiver of the compressed gas for use. A lamp is mounted on the top, which will burn for six, nine, or twelve weeks with one filling, according to the capacity of the buoy. The Trinity House has had two of these buoys under trial, their performances having been reported on as satisfactory. One of these buoys was placed on the East Ooze station, about one and three-quarter miles from the Mouse lightship, on the 18th of last April, and remained at its station until the 28th of January, when it was run into and damaged by a passing vessel. The Trinity House officials report that, during the period named, the light was burning without intermission, although it is stated by the officer in charge of the Mouse light-vessel that, in bad weather, the buoy was at times hidden from view by the spray. The Clyde Lighthouse Trustees have also taken the matter up, and are building gasworks at Port Glasgow, on Pintsch's system, for the service of gas-lighted buoys on the Clyde. One of these buoys has been burning on the Roseneath Patch for some time past, being supplied with gas from London, and a second is about to be delivered by Pintsch's Lighting Company for use on the Clyde. Another of these buoys is about to be despatched by the company to Port Said for use on the Suez Canal. It is seven feet in diameter, and will contain a sufficient supply of gas under pressure to give a light day and night for six weeks. The light burnt will be a red one, and the gas will be stored at a pressure of seven atmospheres, or 105 lbs. per square inch. The estimated cost of the gas is only 2½d. for twenty-four hours' consumption. The process of filling these buoys can be carried out in a few minutes. The reservoir of gas under pressure is floated alongside them in a tender, and the gas is passed from the reservoir into the buoy by means of a flexible tube.

**BEAUMONT COMPRESSED AIR-ENGINE.**—It should have been stated that the blocks of the illustrations of the "Beaumont Compressed Air-Engine," and the "Experimental Engine," in the last number of the *Journal* (p. 386), were kindly lent by the proprietors of the *Graphic* newspaper.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MARCH 30.—“Recent Advances in Electric Lighting.” By W. H. PREECE, M.Inst.C.E. C. W. SIEMENS, LL.D., F.R.S., will preside.

APRIL 6.—“The Discrimination and Artistic Use of Precious Stones.” By Professor A. H. CHURCH, F.C.S. Sir PHILIP CUNLIFFE-OWEN, K.C.M.G., C.B., C.I.E., will preside.

APRIL 27.—“Five Years’ Experience of the Working of the Trade Marks’ Registration Acts.” By EDMUND JOHNSON.

MAY 4.—“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

Dates not yet fixed:—

“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works).

“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

APRIL 5.—“Canada; the Old Colony and the New Dominion.” By E. HEPPLE HALL. JOHN RAE, M.D., F.R.S., will preside.

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Professor A. K. HUNTINGTON.

MAY 26.—“Telegraphic Photography.” By SHELFORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

MARCH 25.—“The Tenure and Cultivation of Land in India.” By Sir GEORGE CAMPBELL, K.C.S.I., M.P. ANDREW CASSELL, Member of Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Third Course is on “The Scientific Principles involved in Electric Lighting,” by Prof. W. G. ADAMS, F.R.S. Four Lectures.

## LECTURE IV.—MARCH 28.

Subdivisions of the electric current. Incandescent lamps. Luminous effects of electric currents in a vacuum, and in various gases.

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Four Lectures.

*Syllabus of the Course.*

## LECTURE I.—APRIL 4.

Introduction. Early forms of twisted, plaited, and looped threads. Ornamental borders of Assyrian, Greek, Roman, and other costumes. Sumptuary laws. Venetian books of patterns for embroidery and lace. Flanders a centre of linen trade of Europe. Spanish and French importations of early lace. Effect of production of machine-made lace upon production of hand-made lace.

## LECTURE II.—APRIL 11.

Needlework upon a material. Needlework rate threads. Venetian needle-point 1 point and tape lace. French needle-point centres. English and Flemish needle-point

## LECTURE III.—MAY 2.

Fringes. Twisted thread-work in 15th century. Early designs for plaited threads. Italian, Flemish, French, and 1 lace. Laces of primitive design.

## LECTURE IV.—MAY 9.

Resumé as to styles of design in hand Traditional patterns. Sketch of the inventions for knitting and weaving thread lace. Differences between machines and laces. Modern hand-made laces at Bunilton, &c.

This course will be illustrated by special Diagrams and photographs enlarged will means of the lantern and oxyhydrogen light

The Fifth Course will be on “Colours and its Influence upon Various Industries.” By R. BRUDENELL CARTER, F.R.C.S. The 16, 23, 30.

## MEETINGS FOR THE ENSUING

MONDAY, MARCH 28TH...SOCIETY OF ARTS

Adelphi, W.C., 8 p.m. (Cantor Lecture)

G. Adams, “The Scientific Principles of

Electric Lighting.” (Lecture IV.)

Royal Geographical, University of London

garden, W., 8½ p.m. Mr. J. B. M.

Bolivia and the Gran Chaco.”

British Architects, 9, Conduit-street,

J. J. Stevenson, “Historical Documents

Institute of Actuaries, The Quadrant

W.C., 7 p.m. Mr. Cornelius Walford

of the Insurance Press in Relation to

and Insurance Interests.”

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, MARCH 29TH...Royal Institution, Alb

8 p.m. Prof. E. A. Schäfer, “The Blood

Civil Engineers, 25, Great George-st

S.W., 8 p.m. Discussion on Mr. Davi

“The Comparative Endurance of Iron

when exposed to Corrosive Influences.

Royal Colonial, Grosvenor Gallery, L

Bond-street, W., 8 p.m. Discussion

Paper on “Imperial and Colonial

Emigration,” will be resumed.

WEDNESDAY, MARCH 30TH...SOCIETY OF ARTS

Adelphi, W.C., 8 p.m. Mr. W. H.

Advances in Electric Lighting.”

Royal Botanic, Inner-circle, Regent’s-p

Exhibition of Spring Flowers.

Chemical, Burlington-house, W., 8 p.m.

Royal College of Physicians, Pall-m

(Croonian Lectures.) Dr. Moxon, “

Circulation upon the Nervous System

THURSDAY, MARCH 31ST...Royal, Burlington-ho

Antiquaries, Burlington-house, W., 8½

Royal Institution, Albemarle-street, W.,

Statham, “Ornament Historically co

sidered.” (Lecture III.)

Civil and Mechanical Engineers, 7, West

S.W., 7 p.m. Mr. G. J. Child, “Lift

&c.”

FRIDAY, APRIL 1ST...Royal College of Physicians

S.W., 5 p.m. (Lumleian Lectures)

“Bright’s Disease.” (Lecture I.)

Royal United Service Institution, White

Captain Walter H. James, “On the

Adapting the Existing Military Forc

ments of the Empire.”

Royal Institution, Albemarle-street, W

Meeting. 9 p.m., Sir Henry S. Main

his Relation to Early Civil Justice.”

Geologists’ Association, University Coll

SATURDAY, APRIL 2ND...Ladies’ Sanitary A

HOUSE OF THE SOCIETY OF ARTS, 4

Richardson, “Domestic Sanitation

(Lecture VII.)

Royal Institution, Albemarle-street, W

R. Havels, “American Humane

Education.”

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,480. VOL. XXIX.

FRIDAY, APRIL 1, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

Fourth and concluding lecture of the third series delivered on Monday, 28th of March, by Mr. W. G. ADAMS, F.R.S., on "The Principles involved in Electric Light." The special subjects treated of in this lecture were the subdivisions of the electric current, arc lamps, &c. The Joel, Werdermann, and Swan lamps, which were lent by the inventors, were exhibited in action. The Swan lamps were exhibited by a Bürgin machine, lent by Mr. Crompford, and a machine was also lent by the Electric Company. The motive power, as used in the lecture, was provided by a Robey engine. Thanks to the lecturer were proposed by Mr. F. J. BRAMWELL, F.R.S., and unanimously.

## ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal for 1881, early in May next. It was struck to reward "distinguished services in promoting Arts, Manufactures, or Commerce" and has been awarded as follows:—

To Sir Rowland Hill, K.C.B., F.R.S., "for his services to Arts, Manufactures, and Commerce by the creation of the penny postage, and for his reforms in the postal system of this country, of which have, however, not been confined to this country, but have extended over the civilised world."

To his Imperial Majesty, Napoleon III., "for his merit in promoting, in many ways, by his exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are his judicious patronage of Art, his enlightened policy, and especially, by the abolition of the tariff in favour of British subjects."

To Professor Faraday, D.C.L., F.R.S., for his services in electricity, magnetism, and chemistry, and his relation to the industries of the world, and his greatly promoted Arts, Manufactures, and Commerce."

To Mr. (afterwards Sir) W. Fothergill Cooke and Mr. (afterwards Sir) Charles Wheatstone, for their recognition of their joint labours in establishing the electric telegraph."

In 1868, to Mr. (now Sir) Joseph Whitworth, F.R.S., LL.D., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, &c., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Ferdinand de Lesseps, "for services rendered to Arts, Manufactures, and Commerce, by the realisation of the Suez Canal."

In 1871, to Mr. (now Sir) Henry Cole, C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the development of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (now Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvement in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to the Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential service in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy, and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong, C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson, LL.D., D.C.L., F.R.S., "on account of the signal services rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science and industrial pursuits."

The Council invite members of the Society to forward to the Secretary, on or before the 23rd of April, the names of such men of high distinction as they may think worthy of this honour.

### LABEL FOR PLANTS.

The Council are prepared to award a Society's Silver Medal, together with a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the best label for plants.

The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award.

Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary not later than the 1st May, 1881.

The Council reserve to themselves the right of withholding the Medal and Prize offered, if, in the opinion of the judges, none of the specimens sent in are deserving.

## PROCEEDINGS OF THE SOCIETY.

### INDIAN SECTION.

Friday, March 25, 1881; ANDREW CASSELS, Member of the Council, in the chair.

The paper read was on—

### THE TENURE AND CULTIVATION OF LAND IN INDIA.

By Sir George Campbell, K.C.S.I., M.P.

My subject being "The Tenure and Cultivation of Land in India," I shall first speak of the tenure of the land. The most prominent feature throughout India is this, that everywhere the soil is held by small farmers not above the position of labourers. Speaking generally, it may be said that there are no large farmers. We found that in India under the native system the rent was in the main retained for the purposes of Government. The Government dealt with villages; those villages were little Republics—the units of the State; they managed their own affairs, distributed the revenue demand, and provided for many common expenses and common necessities by a well-arranged system of local rating. Under our system, the revenue demand has been moderated, but much variety of tenure has been introduced intermediate between the Government and the people, giving rise to very various forms of property. It seems to me that in this process we have done harm, from acting upon English ideas, in two directions. In some parts of India we have attempted to establish landlords, in the hope that they will perform the functions of English and Scotch landlords; in reality they have entirely failed to do so, and the people are under this system more rack-rented than under the native Governments. The free-trade system of free contracts between landlord and tenant

has answered no better in India than in Ireland; in some cases great political evils have resulted, as when through ignorance we have imposed Bengalee landlords over Santals, Gardos, and other aboriginal tribes, the autochthones of the soil in their view, its true owners. In other parts of the country, an opposite course has led to a class of difficulties; there, rejecting the landlord system, we have made the ryots, the cultivators of the soil, absolute owners of the soil, insisting upon the advantage of individual property, we have put an end to the system which, in a village community, the cultivators had the strength to maintain. This course was taken with the best intentions in the world, but it has turned out that in some cases an unaccustomed form of property, given at a low price, and without safeguards and limits, to people who did not understand it, has been treated by them as children treat a gift beyond their power to use. They have made too much use of their credit, they have become involved with lenders, and signed away their rights. They have been sold up by the Courts under our rigid system of law, and sometimes, as in the case of the Deccan ryots, their last state has become worse than their first.

Fortunately the landlord system has been put out to the fullest extent, only in Oude nine-tenths of the cultivators are mere rack tenants at will, without any rights at all. In the Bengal provinces, by the law of permanent settlement the ryots were protected and had fixity of tenure in the same way as zemindars had; and to this day the Bengalis sturdily maintain much of their rights; in the great province of Bahar, recent inquiries have shown, that owing to a combination of circumstances, and of superior, the Bahar ryots have been wholly deprived of their rights and are in a very miserable position. In the North-West Provinces, the Central Provinces, and other parts of India, more or less protection is given to the ryots. I believe that is so in Madras also. I hope Sir William Robinson will give us some information in regard to the position of those cultivators in Madras, who hold under superior property.

The difficulty in regard to the ryots' position in land so imprudently dealt with, has been more in the Bombay Presidency than in any other part of India, and is in some degree owing to circumstances; the excessive variation in the price of cotton, the too sudden extension of cultivation under new settlements, and the sudden increase of revenue when a revision takes place. In the districts of Eastern Bengal, where the system is practically ryotwar, the people seem to get on well, although the titles are now very complex, and in the Punjab, where individual property combined with the village system, I hope the people are really prosperous and contented, in spite, too, of difficulties made apparent by the recent famine. I trust gentlemen in Madras and Bombay better than I do will tell us that, in parts of those provinces the cultivating ryots are pretty prosperous. The moral, however, of the difficulties

have been experienced, both under the landlord system and under the ryotwar system, seems to me to be that it was a mistake too suddenly to introduce our ideas of property, and that a sort of property of the nature of a liberal tenure is more suited, at any rate in the two or three generations, to our rule in India. regards the size of farms, we cannot expect we shall get rid of the poor and small peasant; nor would I, for one, at all desire to do so. always seemed to me that, whether he works or no, and perhaps the harder he works the smaller the small peasant farmer is a more responsible, managing man, than a mere labourer, a better member of society, even in cases where the labourer earns more money. There is no prospect of the general introduction of any system of farming; though I do not desire that, I much prefer that in all countries variety is good, and that the rich, and progressive farmers are very useful as an example to others. Though I have been in the landlord system in India, I think it is very desirable, that for the purposes of large farming, some land should be available for those who desire to undertake it. In Bengal, there is an immense variety of tenure and land that might, no doubt, be made available for money, if it were not for the immense complication of titles; in this respect simplification of titles is the great need of Bengal. It was the practice to give tea planters land, in fee simple, at a moderate price, and in the case of land which had hitherto lain wholly waste, we have been by no means adverse to the system, so long as land-jobbing was avoided; but there was at one time a great tendency to land jobbing, hence which it was very necessary to check. I may say that in India we have nowhere the three-fold function of capitalist-landholder, capitalist-farmer, and labourer, but we have in some cases a three-fold set of functions, namely, the landlord whose only function is to receive the rent; the money-lender and banker, who supplies the capital to the ryot; and the ryot, who cultivates the land. In some parts of the country, comparatively speaking, the landlord combines with his own business those of banker, and in this way is not altogether a useless member of society, though under this system he obtains a dangerously great power over the ryots. Again, where there are no landlords, the common arrangement in India is that for the cultivation of the soil two parties are necessary, the ryot who cultivates the soil, and the money-lender who supplies him with funds, and acts as his banker for him. In this way there can be no doubt that the village majahun is a useful institution, in fact a very necessary institution; very far indeed so long as the laws are not made wholly favourable to him, and so long as he is kept in his place, and not encouraged to combine the functions of money-lender and land-owner. In Punjab, under the village system, the village majahun is generally a highly-prized member of the community; and among the Afghans it is not an uncommon cause of strife and war among the tribes, that one tribe has stolen and carried off the banker, and attempted to appropriate the land for their own villages. The fact is, that under our system of long settlement, by which the risk of seasons and variation of values and prices is thrown on the ryots, it is scarcely

possible that he can carry on without recourse to a banker of some kind. I have always been much in favour of the system of grain rates, valued at short intervals, by which the farmer may be relieved from much of the excessive variations to which I have alluded.

I have now come to the cultivation of the soil, which I am afraid we hardly so well understand as we do the tenure. The great question which has been raised of late years is whether the soil is becoming exhausted at the same time that the population is rapidly increasing, so that grave and dreadful evils may be feared. The population, no doubt, is increasing, but we are still without sufficient data to show the rate of increase; nor has it been made clear whether famines are really more frequent than formerly, or whether we have only had a recent unhappy cycle of famines which may have occurred in former ages, of which we have little information. My impression is, that the exhaustion of the soil is rather a thing which there is reasonable ground for apprehending, than a fact which has yet been made apparent beyond doubt as having actually occurred on a great scale. That a process has been going on, leading to much reasonable apprehension, is, I think, patent. We acquired India after terrible troubles, which had caused very much of the land to lie waste; there were many blanks; the last two or three generations have been filling up those blanks. They found much new land, which they brought into tillage; there is comparatively little left now; there is less room for grazing, less for fallows, more people to feed, and more produce exported. No doubt the soil must be exhausted in the end, if improved methods of cultivation are not introduced. Hitherto the great panacea for everything has been irrigation; but now there are very grave doubts whether increased irrigation, without increased manure, is not too much in the nature of a mere stimulant, and does not cause exhaustion, and grave evils in the end. I think there can be no doubt of this, that limited portions of the soil are very highly and skilfully cultivated by certain classes of natives in their own way. In addition to the higher classes of ordinary native produce, I might take the case of opium, which is cultivated with a care and a skill unrivalled in the world. Again, I might instance the case of potatoes, an entirely foreign vegetable, introduced by ourselves, yet the native cultivators have learnt to cultivate them very much better than we can; but then these special cultivations depend very much on the small quantity of manure which the villages produced, and they can hardly be much extended without additional manure. In truth, we must confess that we are really extremely ignorant of agriculture. Most of us who go to India know very little about agriculture of any kind; and of agriculture under the conditions of Indian soil and climate we know nothing whatever. The consequence has been, that when we have attempted to show the natives how to improve their agriculture, we have generally egregiously failed, and, to use a native expression, our faces have been blackened. In this respect I am afraid we are not improving. The old-fashioned Civil servant, if not so literary as the new class, and, perhaps, not much more agricultural, settled down more in the country, and learned more of native agricultural

habits and ways. Present administrators, I am afraid, know very little of any kind of agriculture, and it is much the same with regard to the native public servant; formerly they knew nothing of English literature, but they knew a great deal of the country; now they are very highly educated, but do not know much more of agriculture than their European superiors. I am glad to hear that a beginning has been made of sending one or two natives to the Agricultural College in Cirencester, and I hope that will be followed up. It is true that many of the free, unofficial Europeans cultivate, very successfully, tea and indigo, but they have enough to do to apply themselves to their own special articles, and have not generally given attention to the ordinary native cultivation.

My view is, that in a country where there is not sufficient wealth, capital, and education engaged in agriculture, to insure the spontaneous improvement of the country, it is the proper function of a paternal Government to do all that it is possible for a Government to do in the way of obtaining information, introducing new staples and new methods, encouraging and instructing the farmers; and when I say this, I speak not merely of an Oriental sort of paternal Government; on the contrary, I would instance the freest of free Governments, that of the United States. As regards the cultivation of the soil, the United States may be said to be a nation of small farmers, and that being so, they have found the advantage of a Government Agricultural Department; they have a most active department of that kind, not only in the various States, but also a Central Agricultural Department of the United States, from which they believe that they derive very great benefit. I, myself, believe that they do. I have seen the very active operation of the agricultural departments. It has then been a very great grief and disappointment to me, that the agricultural department designed by Lord Mayo has turned out to be altogether a sham, and no agricultural department at all. It was made to be a mere addition to the secretariat to the Government of India, dividing with another department the same work which had hitherto been done; it was overburdened with matters entirely outside the functions of an agricultural department, and practically has done next to nothing for agriculture. Our hope was that in one province of India only something practical had been done, viz., in Madras, where we heard a great deal of the successful Government farm under Mr. Robertson. I confess to having been very much disappointed when Mr. Robertson was good enough to give this Society the benefit of his experience. It seemed to me, that in his paper he told us a great deal too much about the tenure of land, and other semi-political questions, in regard to which he cannot be considered a very special authority, and a great deal too little about practical agriculture, on which we did suppose that he was an almost unique authority. I wish then to express my very great hope that her Majesty's Government will see their way to establish in India a real department of agriculture, such as exists in America. I would not be too sanguine that a revolution in agriculture would be very rapidly effected, but I feel confident that much might be done. For instance, no plant is more widely cul-

tivated than maize. When I was in America astonished to see the immense variety and improved sorts of maize, which were exhibited in different places, among which the cultivation enormously improved, whereas in India I heard of a single soul who attempted to in new kinds of maize. To tell the truth, I once confess that I was some 30 years in the service without ever knowing that there was more than one kind of maize. To take another case always seemed strange that while the flax, one of the most widely spread productions, it has never been used for fibre, except, in one small corner of the hills. An attempt was made to grow flax, but that attempt was in the Punjaub, the very driest part of India, as I know, it has never been attempted elsewhere, which is the moistest part, and where, linseed is most abundantly produced, the Government supposes that flax grows best in a moist soil. It seems to me that an agricultural department might very soon do much in the way of introducing new varieties and new staples, and that some information in regard to improved manures, and machinery fitted for cultivators might be worked out.

As to the most profitable staple, I fear that of our old staples do not progress. The export of sugar and silk has rather gone back; and what I have seen of the cultivation of cotton in America, and the great aptitude of the natives there for this cultivation, I very much doubt whether India will ever compete very successfully with America in the cotton markets of the world. I rather think that the best hope for India is in the development of the home manufactures, the article, by which cultivator, artisan, and consumer will be benefited. On the other hand, we well know that, on the whole, there is a constant increase of exportable produce. Wheat is likely to become a very great staple for India, and I still hope it will be so; but the difficulties which I have already alluded to, especially as regards wheat. All the alluvial soils, which grow well without artificial irrigation, have already been occupied. A great extension of wheat cultivation is scarcely possible without irrigation, as some of the canal lands have certainly been very much exhausted for want of manure, and the competition of cheap American wheat is too much in the way. But, on the other hand, India has almost a monopoly of the rice supply of the western world, and there is no limit to the demand for rice. In India, the natives wholly beat the Americans; Indian rice is largely imported into America; we cannot grow too much rice. It seems, too, that rice only needs an abundant supply of water, as it does not exhaust the soil so much as crops. I hope that some of the rice canals, as that in Orissa, which have not hitherto been very successful, may succeed in the end. We have had to struggle with very great difficulties owing to the mismanagement of the private companies who at first undertook them, and demanded exorbitant rates before the canals were ripe for them. There are also very great difficulties in the distribution of water connected with the tenure of land. I hope that there will be room for a very considerable extension of it.

of jute, oil-seeds, and similar great of export in Assam and some districts of Bengal, in the Central Provinces, and in other parts of India. Putting aside here all moral questions, I think it may be a more agricultural question, that the cultivation continues to flourish, and the cotton exported becomes larger year by year, but the substitute for indigo has yet been found—anything else, and I believe that the country may yet go on and prosper if the indigo is only avoided the rock that threatens it, that they cling to a feudal system of indigo by compulsion, when it would better for all parties to give a fair price for it by free contract from free cultivators. Cultivation, notwithstanding its ups and downs, has been an immense success. I am afraid it is down at present, but I do hope that it will not be led into unfair demands for remuneration for the remedy of their labour. Unhappily, there is still a very great evil among the coolies employed in many of the gardens, which imperatively requires the aid of Government, in the case of coolies not free labourers, but bound down for 12 years, enforced by very stringent laws. I am more for freedom of contract between employer and labourer than I am, but what I do see is any demand for freedom for the while there is no freedom for the coolie. One would suppose, from the things that are said, that the Government throw all kinds of unnecessary restrictions in the way of the coolie, while the coolies are free to do as they like. The fact is just the contrary; if a coolie is engaged under the ordinary civil law, the Government in no way restrict him; but if the Government do say is this, that if you have insisted, that you should have the benefit of the most stringent character of contracts of labour by criminal processes, and put into the hands of the planters, then the Government must exercise a power for the protection of the coolies, for the time, not free labourers at all, but able to be sent to the most unhealthy places. I have doubt, then, about the need for new legislation on the subject. My view of the labour difficulty, would be to give very great facilities for the transfer of labour, as hiring of labourers without any penal or other restrictions at all. I should like to see as many roads and railways as possible, to connect the country with over-abundant population with the country where labour is scanty. In particular, very much like to see a cross railway connecting Benares and Behar provinces through northern Bengal with Eastern Bengal and Assam. But the question of migration and emigration of the natives is a very broad and difficult question which I cannot now enter. There is still room for a good deal of migration in the country; it can only be carried out gradually and I am myself much convinced that the people of India, and to the tropical climate of her Majesty, very great advantages are to be derived from an extensive Indian colonization—could only make sure that Indian emigrants should be fairly treated under Colonial

laws, and by Colonial administrators, an assurance which, in my opinion, we have not yet obtained. I think emigration should be encouraged when, and only when, an Indian going to a colony is there treated in the same way as any other of her Majesty's subjects. However, I will not enter on the subject now. I am afraid I have already been too long, and I will only commend the subject of Indian land and Indian agriculture to you as being far more important to the people of India, and to all who are interested in India, than all other subjects put together. I hope that there may be fulfilled that which her Majesty's Government have put forth as their desire, namely, less of wars, and more attention to agrarian affairs.

#### DISCUSSION.

Sir William Robinson thought that the thanks of the meeting were due to Sir George Campbell for his suggestive paper; but he himself felt that the useful discussion of the many subjects thus discursively raised, required more preparation and opportunity for careful argument and statement of facts, than the mere listening to such a paper for the first time afforded to him. As respects the tenures of land by the ryot-proprietors of South India, he had endeavoured to explain their condition—more especially as regards the non-zamindari tracts of the country—on the occasion of discussing Mr. Robertson's paper in this room in May of last year. He had nothing to add to those observations, save that they practically apply, with few exceptions—*ex. gr.* in the Western zamindaris of North Arcot and Nellore—to the condition of landed tenures amongst ryots whose holdings are comprised within tracts of country over which a zamindari settlement still obtains. The rights and tenures of zamindari ryots are similarly, on the whole, very fairly protected against the prevalent attempts to encroach, on the part of zamindars, by the prescriptive character of the ryots' rights and titles—derived in fact from the ancient and prescriptive distribution of village land amongst the freemen of the community—by the consequences of the careful inquiry, and partial registration which preceded the introduction of the permanent settlement in most parts of the country, and by the provisions of the rent-law since enacted by the Madras Government. He would not now discuss such matters as the position of Government in relation to these tenures, "landlords," "superior proprietors," zamindari and ryotwari settlements, and the like, suffice it to say that for all practical purposes the rights and tenures of land were substantially permanent and complete throughout South India; and that this condition of the titles to land had operated so usefully that, within the last twenty-five years, the ryots had, in Madras, added at least 70 or 80 per cent. to the area of land under cultivation, and, of course, the revenue had risen—a fact which showed that the people were satisfied with their tenure, and made very good use of their land. Amongst other things, he was glad to see that Sir George did justice to the banker of India. The money-lender was spoken of as one of the great evils of India, but he thought there was no class of persons more maligned. He was, in fact, the friend of the farmer and collector of revenue alike; without this banker, cultivation could not be so actively pushed forward, or the revenue so punctually collected. It was true that the interest they demanded appeared high, but it was not higher than the accommodation was worth, nor than prevails in other poor and backward countries. In California at the present moment the small farmer did not get his money so cheap as the peasant did in India. The money-lender was a very useful member of the community, and nothing would do more harm than any legislative meddling either with his security or his position. With regard to the ex-

haustion of the soil, he thought too much was said about it; he had been a great deal through the country, and had not observed any serious deterioration, though, of course, a larger use of manure was very desirable there as elsewhere. The fact was that the extension of cultivation was bringing poorer lands under the plough. As regards rice-land, there was no doubt that irrigation brought down large quantities of silt, which was a very valuable manure. He had heard that as much as two tons of alluvial matter to the acre was brought down to Tanjore by the Cauvery, and, consequently, there was probably no exhaustion at all under this cultivation. There was probably no agricultural community in the world which was really exerting itself more heartily, and getting more out of its primitive methods of tilling the soil, than the hard-toiling Indian agriculturist. He was quite at one with Sir George as to the prospective usefulness of a real agricultural department in connection with the local Governments and Government of India, and held that widely-diffused technical instruction in the science and methods of husbandry is a primary duty. He had himself taken an active part in the movement made in this direction in South India, and looked for good, though gradual, results from all examples set to the agricultural population. Allusion had been made to the cultivation of tea and coffee, and it was a remarkable fact that directly we showed India any new product, the natives took it up at once. In the Wynad, where we commenced the coffee cultivation about 30 years ago, the natives had followed so quickly on the steps of Europeans, that, at the present moment, the coffee land cultivated by the natives was quite equal to that cultivated by Europeans. The same with indigo; ten or fifteen years ago large houses in Madras were connected with the cultivation of this plant, but he believed the whole of this culture was now in the hands of natives. With regard to the improvement of agriculture, he did not think we should gain much by attempting to introduce English products; we should be content with endeavouring to improve the native crops suited to the country.

Mr. Charles Campbell agreed with Sir William Robinson that the majahun was a very useful member of Indian society. Few farmers in this country were their own bankers. In Scotland on market days the first thing the farmer did was to pay a visit to the bank. Now in India these money-lenders played exactly the same part as a banker. With regard to the exhaustion of the soil, he never really could see that there was any appreciable exhaustion going on, and it seemed to him that as long as there was a good rainfall, or the river overflowed in the usual manner, the crops were excellent, so far at least as Bengal proper was concerned. It depended on the season whether it should be a bumper crop or a bad crop. If it were a bad season, everybody was inclined to cry out about the exhaustion of the soil, but with a good rainfall one heard nothing about it. Cultivation had been going on in India for thousands of years, and if there had been exhaustion going on, he thought we must have heard of it hundreds of years ago, and there would be no production at all now, because the use of manure was very limited. He was rather doubtful about the utility of the agricultural department till we had ourselves scientifically studied the subject. In truth, we knew very little of Indian agriculture; and he did not think it could be much improved until we knew more about it. We certainly had not improved Indian art, we had improved their manufactures off the face of the earth, and if we attempted to meddle too much with agriculture, though of course immense improvement was possible, we might do the same thing. There were some things which were urgently required. For instance, the introduction of some green fodder was much wanted. Passing through Egypt, one was much struck by seeing the long lines of camels bringing in clover or vetches, or green fodder; and something of that kind was greatly wanted

in Bengal. The cattle there were miserable because they had no decent grass to could hardly call them bullocks at a many districts of Bengal, simply commons which were formerly reserved for holders and village communities for cultivated, and really there was no seasons but dirty indifferent rice miserable cattle to eat. Sir George about the ryots of Lower Bengal and rights, whilst those of Behar seemed the wall; and it did seem that in much worse off. The ryots in certain in Eastern Bengal, were much better places; but in Birbhoom and Kishu districts near Calcutta, nothing could than the state of the ryots; they were helpless creatures as you could conceive done for them, the landlords who were living in Calcutta and squandering the of luxury. He recollected, about ten of these people were dying, simply from and they lost hundreds of cattle from He was rather in favour of the permission His brother (Sir George Campbell) all lords of Bengal not carrying out a land he did not suppose there was any influence the landlords, whether black or white; same in reality, and if they were made duties they did so, but not otherwise. never made the least attempt to make do his duty to the ryot; it had no settlement, and left landlords and the ryots out amongst themselves. There was the rights of any class of ryots. I so far as they had managed to maintain it had been in spite of the Government of the landlords. He had lately been and he must say that every feature was there exactly reproduced, and same remedy which had been applied have the same effect in Ireland. Then on the face of the earth more practical ryot. They all knew what jute was: every article almost of clothing, a few years ago only half a million England. The moment you showed would pay him, he entered into it with an European. It was the same in places it was replacing the cultivation had been mentioned, and they were strict round Calcutta in large quantities the European troops. The soil was for ryot never attempted to sow them and would grow successfully.

Mr. Pfoundes said that allusion was to the United States Agricultural Bureau to have some information about the knew the opinion of intelligent American, as well as having had, some experience of one of the offshoots of bureau. At a heavy expense, and with of trumpets, this bureau was planted was sorry to say that the result in proportion to the expense, and to see anything of the kind trans He had some knowledge of the Commission to 1863, and he thought that India or any other Asiatic who went there treated, if they were only law-abiding self-interest of the colonists would them well, and besides we had English there almost to perfection. Instead bureau, which might succeed fairly under certain conditions, but which, most likely possess all the faults of ism and English red-tapeism brought

thought it would be wiser to subsidise an Acclimatisation Society, with branches in the various provinces, and by Sir means a great deal might be done. When a man, he saw something of the Climatisation Society in Melbourne and Victoria, which did great during the first five or six years of its existence. It was necessary to be very careful in transplanting an, American, or alien ideas of any kind to East-tries. He spoke not so much of India as of the further east; but Sir Edmund Hornby, who rest authority on matters connected with the one occasion told some official Japanese gentlemen strongly advised them in the revolution they entering upon, not in any way to touch the landlords, or native agriculture—above all to be most careful not to interfere with the character of the soil.

Robert Cus, having expressed his disappointment that Sir George Campbell was not able to be it, and his high appreciation of the practical aggressive character of the paper, said there a four distinct tenures of land in India, that of a southern part of India, which Sir William Robinson had alluded to, the Bombay Presidency, the Presidency, the North-West Provinces, and Punjab, in which Sir George Campbell and him had spent so many years. There was essentially some system of tenure there, and the officers of the State took to themselves the credit that their was not a new creation of the English, but a continuation of the old institutions of the people. They did not create great landlords and nobles, as done in Bengal; or break them up into miseries, as in Bombay. They accepted the ryot system, and the village proprietors as the unit. They found the head men of the village representing proprietary, and below them, cultivating tenants of classes, those with rights of occupancy, and tenants of the soil. When they moved in and took the Punjab, came then to a virgin soil and a kindred people, they then found the value of their system entirely altered. They went from village to village, and in a short time the settlement was concluded under the village system which had outlasted dynasties. Many of the village communities had lasted down from the immigration. He did not say that they had existed in India; perhaps they did not, but they had, nearly, been caught alive in North India, and the had been to perpetuate them, not to destroy them. The great secret of governing oriental countries was to let the people alone. Lord Lawrence's maxim was easy settlement and a rapid collection, with no trouble. In this way, they never had any trouble, the people knew there was so much to pay for each thing, the accountant made up the accounts, and the man paid the bill. If they attempted to interfere much with the people, as, he was afraid, had been done in Bombay, dealing with each individual, and taking the rent-roll of some thousands of individuals, there was much room for oppression on the part of native rulers. In the North-West Provinces they dealt with villages by their head men, and that was the secret of their prosperity. Everybody who had studied the use of India must think of Ireland, for the circumstances were, in many respects, the same, and the remedy should be applied to both. In India they insisted that there were in the land two distinct rights as rights of the proprietor and the rights of the tenant. Both were able to co-exist. They recognised the landlord had a limited right in his estate, and the tenant had his right to the produce on his payment; the landlord paid the revenue to the State; the rights of the tenants were guaranteed, and nothing of the same kind would have to be done in India. He agreed with what had been said about the money-lenders or bankers; the business of the country must be carried on without them. He doubted whether

it was the business of the Government to meddle with agriculture; we had enough to do to collect the revenue and keep the place; the great thing was to let the people alone, though you might have a model farm if you liked as an example. The people knew their own business best; they had been going on in this way for 2,000 years; the land never got a fallow, but it produced magnificent crops, sometimes two in one year. He believed the people were quite sharp enough to guide themselves, and he doubted whether an agricultural department would be of any use. The great enemy of India was Manchester; and if India were governed by an independent Legislature, such as the Colonies and the American States had, they would never allow their rights to be trodden down for the benefit of a great manufacturing town in England. He was convinced that India suffered from the influence of deputations coming from Manchester to the Secretary of State, and pretending that it was to the interest of India to do so and so, when it was really their own pockets they were thinking of. Indian officials, whatever their faults might be, stood up for the people of India, and he hoped that the feeling would grow, that India ought to be considered as a great empire of itself, and not merely as a province of England.

Mr. Pal Chowdhuri said as he came from Bengal, he would state what the land system of that district was. By the permanent settlement, the zemindaris held large tracts of land, the rent of which was fixed, and they let it to the actual cultivators. These cultivators held the land under two different systems, one what was called the lease system, where the land was leased out permanently, or for a certain length of time, and another system under which the tenant only occupied for one year, and when the crop was over, he might, if he liked, leave that piece of land and go to another. There were a good many villages where there was no fallow land at all, and there the ryot would be obliged to cultivate the same piece of land again. There in such places the lease system was more prevalent, but leases again might be permanent or temporary. Where it was permanent, the rent could not be enhanced by the zemindaris, but by the temporary lease at the termination of the lease the rent might be raised or not, according to the condition of the village and the land. He agreed with Sir William Robinson that the money-lenders were most useful members of society, especially in Bengal, where the rent was payable at a certain fixed date, and if the owner did not pay, his property must be sold, so he was obliged to collect the rent from the ryots. If there were no such class as these money-lenders, property would be continually passing from hand to hand by forced sale. He agreed that there were some who did not treat their customers very well, but on the other hand some were very lenient, and went on lending to persons who could not pay their debts even for years. If there were a few persons in a village who could not pay their debts, the money-lender could not stop lending to them again, or the whole village would come to him and insist on his helping those poor persons. With regard to high cultivation, he did not know whether the time was come when it could be introduced into India profitably. Of course manuring and high farming increased the produce, but if a farmer could cultivate a piece of land for ten rupees which yielded him fifteen, he then got five as his nett profit. If he cultivated it highly, it would cost him twenty rupees, and instead of fifteen he would get twenty-seven, which would give him a nett profit of seven rupees from the same piece of land instead of five; although his profit was increased by two rupees, he had spent twenty instead ten, so that the per-centage of profit was decreased from fifty per cent. to thirty-five per cent.; and as there were plenty of fallow lands not yet cultivated, it would pay him better to take another piece equal to the former, and expend the extra ten rupees upon that, in which case he would still get his fifty

per cent. profit. So long as labour was cheap and land abundant, he did not think high cultivation would be profitable, though no doubt the time would come when the European system would be necessary.

Mr. A. Rogers (late member of the Bombay Council) said the presidency of Bombay had been much looked down upon by some speakers, and described almost as a sink of iniquity, in which the rights of everybody had been ignored, but he could assure them that that was by no means the case. Where they had found proprietary rights existing these had been preserved, and it was by no means the case that a simple ryotwari tenure existed throughout the whole Bombay presidency. When the country was first taken over, it was not found that there were hereditary farmers to any great extent, but those who paid the revenue of the villages were persons to whom the right of levying the rent had been let out by the Government of the day; but where they were hereditary their rights had been preserved. The system amongst the Mahrattas was that of farming out the revenues to the highest bidders, who were often court parasites. When the new system was introduced, they endeavoured to protect the ryots against the exactions of those who were merely farmers of the revenue, and that was how it came to pass that the village system broke up in some parts of Bombay. This was specially the case in the Deccan, and in a portion of Guzerat. Having had a great deal to do with the land settlement, he could say that a system was introduced which enabled each man to stand on his own feet, and work for himself, which had been of the greatest importance to the people. In many cases they had rescued the agriculturists from virtual slavery. There were certain classes who were called Nirwadars, in Ahmedabad, Bhagdhars, in Broach, and Talukdhars, who had certain proprietary rights, which had been preserved; but under these heads of villages there were other tenants, who had rights adverse to them—tenants who had customary rights, just as there were in other parts of India, and those had been most strictly preserved. With regard to the introduction of the agricultural department, he thought they should be very careful how they attempted to interfere with the systems of native agriculture. The natives knew very well how to take care of themselves. Much had been said about introducing the system of deep ploughing, but he thought it should not be attempted except with very great caution. Such a system had never existed in India, but if it had been the right system, he thought the natives would have found it out before now. There were, doubtless, fertilising principles lying deep in the soil which, if they were turned up to the surface, and exposed to the sun for seven out of the twelve months, would disappear; whereas, now nature provided that they should remain deep in the soil, and provided the plants with sufficiently long tap roots to reach them. He also agreed with the usefulness of the majahun.

Mr. Shore desired to say a word or two on the land system of Orissa, a province very interesting in many respects, both from its natural features, and the state of things existing when the English conquered the country. It offered a contrast to the rest of Bengal, in this respect, that it had not been subjected to the permanent settlement. They had certainly committed the same error—if it was an error—to some extent which Lord Cornwallis, or the previous Governor of Bengal, committed, in recognising at once the classes which were employed in collecting the revenue as the proprietors of the land. It was quite true that in the permanent settlement it was stated that the rights of the ryots were to be ascertained and recorded; but that was not done. In Orissa there were more hereditary rights on the part of the zemindars than in Bengal, because the country had never been so thoroughly conquered by outsiders. At first they made a great bungle of it; and partly in consequence of the oppressive demands made

on the land, there was a which opened their eyes to serving the rights of the people detailed and minute settlement principle of which was exact have been recognised in the not in practice, and had been They recognised the rights of hereditary and indefeasible revenue to the Government insure the rights of those who There were two descriptions and hereditary resident ryots their property absolutely as as they paid their rent, which by the zemindars by one fifth to the land for which they allowed to have a considerable rent. These people had well of the demands upon the ryots had not these advantages rents raised upon them, not only by the middle men, of whom some of whom had a percentage of the produce of the rent quantity. This system, on test of experience extremely new to the country, there was a great at that time, instead of their land, the great proprietors of for ryots, and, in some cases ryots, and gave them hom majority of cases, it was that they desired to have on the known cases of affrays between for the possession of these however, of the increase in position of things was now tion was now more for land was another peculiar tenure Orissa, in the sacred district Juggernaut. Mr. Long said was now twenty the interior of F

Empire employed to carry out the serf emancipation, and the system which had prevailed in India as immemorial had prevailed in Russia for ages, and had worked wonders. Had that system helped further, we should not have had the which occurred lately, but, unfortunately, it and a reactionary system took place. Each is representative, and these representatives of county assembly, and that led up to a assembly. It should have been carried further in assembly, but that was not attempted; still had been done in Russia by the system. and to the Bengal ryots, they owed an of gratitude to Sir George Campbell, who, and much opposition by the educated classes, was the friend of the ryot, carried out reforms and carry his name, with that of Sir J. P. and to posterity as the benefactors of Bengal.

Mr. MacLagan, B.E., with reference to the which had been made regarding exhaustion of India, did not think they had yet sufficient data to form any conclusion on this subject. It was one matter which greatly affected the of the land in certain parts of the North-West and the Punjab, which had not been alluded to was, that a certain injurious salt, called its appearance on the surface of the ground, in large areas out of cultivation. It has extensively on lands irrigated by canals, and where the irrigation channel was a little level of the country. The water sank into and percolating there arose to the surface with it this injurious salt. The salt is chiefly soda. It has sometimes been supposed to canal water, but the same water irrigates without producing salt. It appears to be and to be brought to the surface by the men near the surface, it comes out after rain, in ravines in the neighbourhood of Lahore. Mr. W. Sleeman, in his "Tour in Oudh," he occurrence of salt in that province on lands, and describes the remedy there which was to divide the field into very small little raised banks between; these were water, which gradually sank into the soil, the salt with it, sufficiently to allow at least be raised, and, when necessary, the process. Of the lands which have been watered in the Jumna Canal, there are many square which, from this cause, no crops can be grown, which the salt is so copious as to have the of snow. On salt land it has been found in kinds of vegetables can be grown, but, generally, the land so afflicted is thrown out on. The matter has attracted much notice, and the "Liberation of lands from salt" has been the much correspondence. It continues to mention as a matter of some scientific interest, practical importance.

Mr. MacLagan said he thought it was impossible for him to have had to deal with the land revenue, to give any opinion on the subject of land without listening to, and not having had that he would not touch on that point; but with the remarks made on the subject of agriculture was strongly of opinion that the natives had much to learn, and he concurred in the of Sir George Campbell. Most of the gentlemen held a different opinion, and seemed to think the very little to learn; but still, from their own thoughts their conclusions might be disputed. The natives were very quick to learn, and when introduced a new process, they immediately adopted it, which evidently showed that they could and were being taught. He was much interested by a dispatch written by the late

Lord Mayo on the 6th of April, 1870, from which he would read a few sentences. Lord Mayo said that, "of all branches of Indian industry, agriculture, which constituted the occupation of the great mass of the people, was by far the most important, and he believed it to be susceptible of almost indefinite improvement." Again he said, "for many generations to come, the progress of India in wealth and civilisation must be directly dependent on her progress in agriculture;" and again, "it was hardly too much to say that a scientific knowledge of agriculture in India had not at present any existence." Those were very strong words; and many old Indians with whom he was acquainted said they were incorrect; but, on the other hand, many others who were well versed in agricultural matters, considered them perfectly true. He did think there was much to be done in the way of improving agriculture in India.

Mr. Long said he was for several years a member of the Council of Agriculture; and they found the natives were very careful in learning, but they did not understand principles.

The Chairman said some gentlemen had spoken as if there were an idea of compulsion in this matter; but nothing of the kind was ever dreamt of. All they wished to do was to show what could be done, and leave the natives to follow what appeared to be for their good. A relative of his own, when some years ago, went through a regular course of agriculture at Cirencester, and he heard he had recently been giving lectures on agriculture in Katimour, and hoped good would result from them. He must take exception to the remarks of Mr. Cust, who had attacked his old friends in Manchester. What harm had they done? The only harm they could have done was in depriving India of a portion of revenue from import duties; but surely if Manchester had given India goods 5 per cent. cheaper than before, it was a very good thing for the consumer. Again, if Manchester sent large quantities of cotton goods there, she imported large quantities of cotton in return, and had greatly increased the demand for its cultivation in India. Speaking from some personal knowledge, he could state that no part of the kingdom had been more earnest in pressing on the Indian Government the necessity of constructing works of irrigation, railways, and every improvement of that description, than Manchester. The men of Manchester were no more selfish than other people, and he could only say that if India had men as energetic, as enterprising, and as industrious as they were, she would do exceedingly well. In conclusion, he proposed a vote of thanks to Sir George Campbell for his interesting paper.

The motion was carried unanimously, and the proceedings terminated.

#### SEVENTEENTH ORDINARY MEETING.

Wednesday, March 30th, 1881; C. W. SIEMENS, LL.D., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Culley, William Richard, 15, Maryon-road, Charlton, S.E.

Dale, George Williams Melville, Ellerslie, Nether-street, North Finchley, N.

Davis, Moses, 27, Wellclose-square, E.

Knight, William Duncan, Avening-house, Greenhill, Hampstead, N.W.

Mackie, John, 2, Victoria-villas, Queen's-road, Reading.

Pope, Joseph John, M.R.C.S., 4, South-crescent, Bedford-square, W.C.

Rowan, Arthur Hill, 6, Westminster-chambers, S.W.

Thornhill, W. George, 36, Eastbourne-terrace, W.

have worked hard in this field, and have led in producing engines which, by autogovernors and by other means, provide all requirements that the electric light demands. It would be difficult to over-estimate the good that has been done in this direction by the committees instituted by the Royal Agricultural Society. The small engines that distinguish the engines, are almost entirely due to the success attained by these annual trials. Instead of the power requiring 7 lbs. and 8 lbs. of steam to produce it, it is common now to find engines producing one-horse power by even 3 lbs. of steam in some engines 2 lbs. per horse-power has been attained. It is strange that nothing has been done to supersede steam as a generator of power. It is well-known that the specific heat of steam is higher than that of every known substance, and it is not beyond the reach of theory to assert that there are other liquids whose evaporation would produce the same power with a very much smaller expenditure of fuel. There is a vast field for research in this direction. The gas-engine is a economical source of energy, and has been successfully applied to electric lighting in places. At the Docks in Newport, South Wales, a gas-engine has been in use for nearly two years with great success; and it is worthy of note that 100 cubic feet of gas per hour gives a candle-power of 300, that same gas applied to an engine gives, in electricity, a candle power more than three times greater, namely, 3,750 candles. Here we are able to maintain gas dividends.

Water is another convenient source of energy, and you can find it available. Sir William Armstrong, at Craigside, near Newcastle, has a brook for this purpose, and, by the aid of a turbine, produces a force giving six-horse power. In fact, he says "the brook lights his

not aware yet of air having been utilised for this purpose, except when heated in the calorific mass at the Lizard Lighthouse, which is a very economical, useful, and very suitable in isolated places where it is difficult to provide power. It is, therefore, clear that some progress has been made in the economy and adaptability of motors for electro-dynamics to produce the electric light.

With regard to the generator of electricity, the method by which the energy of steam or water is converted into electricity, after Professor Adams, I leave it remains for me to say. There are several different machines. The difference between each machine is the difference between the twinned wheels of the eddies. Each is specially adapted for its particular work, either by a variation in the shape of the wheels, or by a variation in the way in which the wire is wound, so as to produce a certain tension in the current produced to suit the particular light required. The efficiency of a machine is the amount of energy which is converted into current, and it has been shown that the Siemens and the Gramme machines convert 90 per cent. of the power is converted into current. It is easily demonstrable that the economy in the use of small machines, and the difficulty to understand the reasons that some people to speak of the value of the machines that have been constructed in

America. In fact, in this department, a great deal of time and energy is being wasted in trying to gild refined gold. Changes are being introduced for the mere sake of change. The improvements that have been made have been improvements in detail only. Broadly speaking, there are two classes of machines, those which produce continuous currents, and those which produce alternate currents. Very little advance has been made in the efficiency of the earliest forms in every case; and I learn from Mr. Douglass, of the Trinity-house, that the original Holmes magneto-electric is still in use, and doing good work, at the Souter Point and South Foreland lighthouses, and that a De Meritens magneto-electric alternating current machine, of similar type, has been under trial at the Lizard for the last four months, and that he is greatly pleased with its efficiency and reliability. The De Meritens machine is an excellent one, and one of which we shall hear more. The trials made for the Trinity-house showed that more efficiency was obtained by joining up small machines in multiple arc, than either by the use of a larger machine, or by the same machines joined up in series. This is a point that has escaped the notice of recent experimenters in this direction, and it is well worth their serious consideration.

The battery has been discarded as a generator of electricity from its want of economy, but there are hopes that secondary batteries will be introduced for the purpose of storing-up this force. No advance has yet been made, however, towards the practical attainment of this desire. Many attempts have also been made to utilise the thermopile, but in all cases it has been shown that the electromotive force produced is too low. The thermopile has this advantage, that it is wonderfully durable. I saw, last week, one which has been in use for four years uninterruptedly, night and day, without intermission, and it still gives out electricity with all its pristine vigour.

The conductor is the broad road along which electricity flows to produce light at a given point. In all cases, from its superior conductivity, copper has been selected. Sometimes this copper wire has been carried overhead and sometimes underground. Where it can be carried overhead, it has the advantage over underground that, as the heat radiates into the open air, the wire itself becomes cooler and conveys more electricity. In practice, the purest copper is used, and wire of the largest dimensions consonant with economy, for the resistance or obstruction to the flow of electricity must be maintained as low as possible, to prevent waste of energy. In the different experiments which have been carried out in London, one feature noticeable to me has been in some cases the utter ignoring of the experience gained in telegraphy. The way in which wires are suspended, and hung, and moved about, is to the mind of the telegraphist simply disheartening and appalling. On the Metropolitan Railway the wires were so decayed, and rotten, and ill-used, that they had to be removed, and the lighting of the Victoria Station of the Underground Railway was abandoned. The currents used for electric lighting are more than 3,000 times greater than those used for telegraphs. We have great difficulty in maintaining the small currents used in telegraphy along their proper course, and the

small defects that have, in thirty years' experience, made themselves evident to us, are simply magnified in their hurtful effects 3,000 times when applied to electric lighting currents.

Electric currents have also a peculiar and serious influence on wires passing in their neighbourhood. It is an influence called induction, and one that produces serious disturbing effects. In fact, so powerful are these disturbing effects, that very great fears are entertained that it will be impossible to maintain electric light and telegraph circuits close together. Recently at Holyhead telegraph communication was completely broken down along a wire that ran side by side with the wires conveying an electric light, during the time the current flowed to produce the light. We of the Post-office are watching carefully for any interference by electric light currents in this respect.

Why do electric currents produce light? Light and heat are mere terms given to what are really similar operations. Certain undulations impinge on the retina of the eye, and give that sensation which we call light. They fall on our skin, and produce the sensation of warmth. They are incident on certain salts of silver, and produce photographic pictures. The flow of electricity means the generation of heat. The production of light is the accompaniment of intense heat. In fact, the brighter the light, the intenser the heat. The art of producing brilliant light is the art of producing high temperature. There is no greater illusion extant than that the electric light is a cold light. The electric arc is the greatest source of heat known. Our worthy Chairman has shown us how it can reduce to liquid the most refractory metals; and at his country house, near Tunbridge Wells, he has kept a stove-house at 70° by its aid. Professor Dewar measured the heat radiated by the light he used, and found it sufficient to produce three-horse power per minute; hence electric currents produce light because they produce intense heat.

Now, this heat can be produced either by causing the electricity to fly across an air space, in which case we have light by the arc, or by causing it to flow through a small wire, or a carbon filament, which offers obstruction to the flow, and produces light by incandescence.

We have burning to-night several specimens of each kind. The forms of arc lamps are very numerous. In every case carbon rods are opposed to each other, and they are disintegrated and consumed in the fierce blast to which they are subjected. The lower pole—the negative—acquires a temperature of 3,150° C., it is broken up and fired with a fierce bombardment of white hot molecules across the air against the upper pole—the positive—which is beaten up by incessant impacts into a higher temperature of 3,900° C., the arc itself being 4,800° C. On account of the irregularity in the character, and, therefore, the consumption of carbon, and the variation in the strength of the current, various ingenious appliances have been adopted to obtain steadiness and uniformity in action. Mechanism, clockwork, electromagnetism, gravity, and all kinds of contrivances have been called in; in fact, of arc lamps, their name is legion.

A remarkable attempt was made by Jablochhoff to dispense with mechanism altogether in his candle, but though many thousands of them are in use, it is doubtful whether the candle system

will be permanent, for it is expensive and wasteful. M. Jamin has recently taken a step in advance in this line, and the trial of his lamp is being eagerly watched.

We have not yet obtained perfection in the lamp. We want brilliance, combined with absolute steadiness, and the durability of a winter's snow. Great steps have, however, been made in simplification of parts and smoothness of action; but lack silence and steadiness.

Many of the defects of the arc light are compensated for in that of incandescence. Here we have something that is beautifully soft, absolutely noiseless, perfectly steady, a light that brings up Nature in all her true colours and purity shall not readily forget a dinner party given by Mr. Spottiswoode, the President of the Society, a short time ago, when his room was illuminated by Mr. Swan's lamps. It was only fascinating, but fairylike and lovely, as if felt in a dream. We have had a sample of this here, and the beauty of the light grows more apparent. The incandescent light is, however, at present an expensive luxury. It requires a considerable expenditure of power. For instance, Sir W. Siemens strong finds that six-horse power supplies the giving altogether 925 candles. Six-horse power arc lights would give over six thousand candles. However, we must not grumble. Rapid progress is being made in this field. Maxim, Edison, in America; Swan, Lane-Fox, and others in England, are working hard, while Gordon Joel are working in an intermediate field, where the prospect appears of a happy compromise between the arc and incandescence. We have, to-night, an illustration of the burn of the Joel lamp—a modification of that introduced by Mr. Werdermann.

A good many wild statements are made of the light-giving power of these different lamps. A standard sperm candle may be a very good one to measure gas by, but it is a very poor standard for the electric light. Of course the advocates of the electric light over-estimate their case, would not be human nature if they did not; but their divergences are wonderful. Thus, the Glasgow committee makes one horse-power produce 1,254 candles; the Trinity House, 1,254; a Paris Commission, 2,500; a certain Anglo-American Gas Company, an unknown quantity!

We have two natural standards to refer to, light and moonlight. We have various physical forces to appeal to for measurement, photometry, records, the production of heat, the estimation of shadows, &c., but the standard of the sun remains an *ignis fatuus*. To estimate the value of a light, you must not look at it; you must turn your back to it; you must try and read small print by it, and then you will find what a good standard would be to find some means by which we can estimate the illumination of a square foot or square yard. We want not only a new standard of light, but we want a new system of photometry. Efforts have been made to estimate the intensity of the light radiated by the size of the crater on the carbon rods; but this mode of measurement is empirical and illusory, for it varies with the character of the carbons and the currents used.

A word about that "philosopher's stone," *elixir vite*, the subdivision of the electric

sitment? It means that certain gentlemen, from one central spot, to distribute gas, as they do gas and water, throughout the city, so as to furnish great cities with cheap, abundant light. "'Tis a consummation to be wished.'" Now I am one of those who do not believe in the word "impossible," and that with our present knowledge, this is insoluble. There are those who don't who think I am an obstructive lunatic. What are the facts? Numbers, thoughts, can be manipulated anyhow—hence Whig High Church and Low Church, but facts are inexorable. Sir Armstrong, can only keep 37 lights going; could only show 12 lights; Professor could only produce from the most powerful machine, by calculation, 140 lamps. the subdivision? The advocates of subdivision assume an inexhaustible source of electricity. Their opponents reply that there is but a limited source of energy in every dynamo. Subdivision means loss of power, waste and useless expenditure. We are not William Armstrongs, who can say of "I can afford to waste that which nothing." One ardent disciple of subdivision, "There is practically no loss in the electric light produced by this means (subdivision)." Now, is the production of light when you ought to have 6,000 candles the production of 3,600 candles on the bankment, where you ought to have 6,000? Our dynamo-machines have their power on earth, either of subdivision or multiplication, can make the machine do a given amount of work. It may waste time, and, probably, very soon powerful machines and lamps of lower power may enable us to light up a greater circuit, but this is not subdivision, but multiplication. I anticipate more advantages from subdivision of power, and I look forward when I shall have in my own house a simple dynamo-machine, working my lamp, and no one else's. I have not the ambition to be dependent on electric light, generated miles away, and liable to all the accidents to which I, as a telegraph engineer, am subject, and painful experience. Having got our light, the next question is, how we utilise it? This question, as far as illumination is concerned, is about to be solved for us in a very interesting way by the Siemens system. We have, first, the centralised system of Dr. Siemens, where one machine works a great number of lamps, raised like a small moon upon a high mast; and we have, secondly, the distributed system of the Brush Company, who have existing street lamp-posts, one machine works a great number of lamps. I have no doubt myself, from my own observations, that for symmetrical lighting of large areas, such as docks, parades, &c., the former is the best; but for long streets and thoroughfares, the latter is superior.

The arguments apply for internal illumination. Nothing can be more perfect than the Siemens system at the British Museum, while the distributed system would alone meet the case

of such a place as the Waterloo Railway Station. For the former we want height and space; for the latter, length and lowness. In fact, the longer and lower the place to be illuminated, the less is the intensity of the light required; and when we come to long rooms and passages, we possess all we require in the small incandescent lamps. It is not difficult to show that such conditions may arise, even in external illumination, that a few small lamps, well distributed, will illuminate better than one or two powerful ones.

An eventual feature in practical lighting is the proper scattering or diffusion of light, by shades, screens, and reflecting surfaces. There is an archway at Waterloo Station that is wonderfully lighted, owing to the white glazed tiles on its sides, forming such admirably reflecting surfaces. We want to emulate the diffusion of daylight. It is marvellous how whitewashed surfaces do this. Well selected globes act as though they were self-luminous—they scatter light and prevent shadows.

The reason why daylight is so diffused, and the light searches out the inmost corner of our cupboards and our drawers, is simply that practically the whole sky becomes the source of illumination, light radiating from each point. One interesting question that will be solved by the great experiment commencing to-morrow in the City, will be the relative efficiency of different lights in penetrating fogs. It is a point open to the observation of every one of us, that the electric light upon the Thames-embankment exhibits no more power in penetrating fogs than gaslight. The reason of this is extremely simple. Light, as I have previously explained, is due to the undulation of matter. There are waves and waves; some like the mighty ocean swell, tossing the *Great Eastern* like a cork in a basin; others are reflected from the side of the cork, as the billows of a storm are tossed back by a solid pier. The colour of the sky is due to the reflection of the tiny blue waves, by excessively minute material particles floating about. The red sky at night is due to the unimpeded transmission of the larger red waves, the smaller ones being checked; hence the dull red of the round sun in a mist, and the destruction of the smaller rays of the electric light, which lend it that bright and brilliant violet tint in clear weather. For the same reason that the penetration of the electric light is no greater than gas, its illuminating power in its immediate neighbourhood is more. For these small rays which had been checked by material particles from penetration are reflected back to the immediate neighbourhood of the light. There is a great difference between the quantity and the intensity of light. There may be light of very low intensity, but yet of such large quantity as to penetrate to a considerable distance. A ship on fire at sea, for instance, is seen to an enormous distance; and it must not be forgotten that the law of squares, by which the relative intensity of light is determined, is true only for points; it is not true for surfaces. A large flame of gas, though its intensity is so much less, may be as luminant as a point of electric light. Beacon fires, though of very low intensity, are visible very far. In fact, if we increase the luminous area as we recede from it in proper ratio, we shall maintain the same amount of illumination; hence the great failure of photometric measurements to which I have

alluded. A photometer measures the intensity of light, not its quantity.

It is important to acquire some experience from the actual users of the electric light, and to know what amount of business has already been done. For instance, there are nearly 300 Gramme machines in use in England generating light. There are many more Siemens's, while the Brush people have already installed many machines and lights.

The Trinity-house, who have applied the electric light to lighthouse purposes, have at present confined its use to Souter Point, South Foreland, and the Lizard. They find that the expense involved in the installation of the light is very considerable, and it cannot be adopted without very strong and powerful reasons. Perhaps the greatest extension in the use of the light has been for naval purposes. Nearly all our present ironclads are supplied with the electric light. The last addition to this list, the *Inflexible*, will have no less than two Brush machines, each producing sixteen lights. These machines will be arranged to work together or separately. There will be lamps in the citadel, in the engine and boiler-rooms, in the steering platform, below the torpedo department, in the magazine and shell-rooms; they will be used for buoy lights and mast-head lights, and probably, as there will be plenty of accommodation on board for the production of electricity, the cabins will be lighted with some incandescent lamps. The *Minotaur*, again, is fitted with sixteen Brush lamps; and, in fact, for torpedo purposes, the light is not only useful, but absolutely essential. Last year I had the pleasure of spending some time in the Mediterranean on board a ship laying a submarine cable between Marseilles and Algiers. Our operations were carried on by night as comfortably as by day, by the aid of the electric light.

Libraries, again, have become a useful field. Reading by gaslight is irksome; reading by the electric light is simply delightful. The Picton Gallery at Liverpool has been so lit for a long time, and the British Museum is now permanently illuminated by five arc lights, which fully answer the purpose. This has enabled the authorities to keep the reading-room open daily through the winter till seven o'clock, and only on one day (and that within a short time of the hour of closing) have the lamps failed, the failure being due to a want of proper fuel for the engines. At South Kensington 32 Brush lights are used with great success, and afford every satisfaction, not only as a luminant, but in an economical sense.

Railway stations are gradually adopting the lights. The Liverpool-street Station of the Great Eastern, the Paddington Station of the Great Western, the Waterloo-bridge Station of the London and South Western, the Charing-cross Station of the South Eastern, the Bricklayer's Arms (Goods) Station of the South Eastern, are being practically and effectively lit, and the St. Enoch's and Queen-street Stations at Glasgow, as well as the Victoria Station at Manchester, are equally successfully being lit.

Again, we find seaside resorts availing themselves of it for the illumination of their parades. Blackpool, for instance, has, with great enterprise, lit up the whole of its parade and piers with great success.

The new Albert Docks on the Thames, the Alex-

andra Dock at Newport, the Mersey Dock at Liverpool, are all spreading the use of electric light with considerable speed. I was surprised to find the Belle Vue Gardens at Manchester, a pleasure resort that reminded me of the old Surrey Gardens we used to have at home, where, without any expert assistance, the managers, the Brothers Jennison, had installed several lights themselves, and had done so with neither trouble nor difficulty in the matter.

It would be impossible to make a list of the numerous works, mills, dye works, &c. that have been supplied with lights worked by electricity. The Iron Works at Barrow, for instance, have been very extensively employed in it; and the office was probably the first place where the introduction of the electric light for such purposes. Shops and warehouses in parts of the country are now being supplied with Whiteley's, Shoolbred's, Nicholl's, Crocker's warehouses in Friday-street, &c. in other places, and now we find that the rating of the illumination of their shops and spaces. I never pass that wretched site of old Temple, wishing that the heraldic beast that was there were removed, and supplanted by a bronze pillar 30 or 40 feet high, with a miniature sun. It would not be so useful as a memorial more ornamental, but it would be useful as well.

One of the most useful purposes for which electric light has been applied, is that of curing the wretched fogs of winter, that quench the actinic power of sun rays, but it is a large extent in carrying out what is called the Woodbury process. The electric light is as powerful as sunlight, i.e., it does not act with the same rapidity. Electric light takes three times as long to print gels as sunlight. The Woodbury process, as the sun Lock and Whitfield assure me that they know what they should have done, is a sunless winter without its aid. A person's exposure is for one hour in the sun, but in the electric light, is a matter of minutes; if the quality of the results are as good as in the sun, however, has an advantage, due to the greater quantity of light that it emits.

Perhaps, however, the most important use of electric light from a scientific rather than a practical point of view, is the application of it to horticulture. The Chairman, of this light to horticulture. He has found that it fulfils all the requirements for the growth of plants and ripening of fruit. He has at his country seat, near Tottenham, carried on a very large series of experiments, and has created quite a sensation in the horticultural world.

Notwithstanding these great uses of electric light, it must not be forgotten that electric light has its defects and its disadvantages. It is not gold that glitters. The intense heat it emits is a troublesome. The use of electric light is at times wearisome. The impurities in the carbon and irregularities in the current produce a tantalising effect, has an unfortunate habit of shining when it is most wanted. More

durability remains yet to be solved. Many said it and abandoned it. In some cases economy is unquestionable; but there are where careful persons have shown that gas, for economy, surpasses it. It is question-begging, in some cases, the electric light does not do the eye. The experience, however, of the Museum is entirely in its favour. Nevertheless, I have myself suffered much from the light; true it was in experimentation, the same thing might have happened with the electric light; but rumours do exist that eyes have been affected, and probably sufficient time has elapsed to solve this question. The electric produces, also, nitrous acid and other noxious gases, as is shown in the condition of the lamp. The incandescent lamp, is, however, without this trouble. The powerful currents that cannot be carried over buildings and without incurring danger from fire and to have been proposed to utilise the electric in the mines, but, to my mind, one might as well train of gunpowder along a mine gallery, all a dangerous one, as a wire conveying powerful currents of electricity as a light source that wire be most carefully protected. The disturbance due to induction I have already mentioned. Nevertheless, in spite of all these defects, as great and manifold advantages. The effect of a well-lit room is simply enchanting. The effect of the light for the transaction of business, the selection of colours, and the ordinary conditions of life, is simply superb. The effect of the light is one of its great merits. It is no joke; but probably its greatest advantage found in the influence it exerts on the air. We all know that the air is vitiated to a great extent, by the mixture of carbonic acid. It has been well shown that to be in good health there should be not more than one part of carbonic acid in ten thousand parts of air. When the proportion reaches ten parts in ten thousand, the action of the heart is affected. When this proportion runs up to from thirty to thirty volumes in ten thousand, it occurs, and in higher proportions, rheumatism, bronchitis are the consequences. Now, one cubic foot of fresh air per hour per person, consuming three feet per hour, are necessary to maintain your health; in fact, in our offices at the General Post-office, we require three million feet of fresh air per hour to provide a healthy atmosphere. The electric light does away all the necessity for this ventilation, does not vitiate the air. We have Glasgow, where we have applied the electric light, that all these causes of trouble have been engendered, more work is done out of men, and, in point of fact, the experience of others shows that the electric light does itself even in the increased work that is done out of labour in consequence of it only is the health of the subject improved; men are able to do more work in a room from the influence of this pure light than the impure light of gas. We still want economy combined with steadiness and durability. These things made have not been so much in view, as in the improvement of details, and the knowledge of electrical measurements

and of the relations that exist between electricity, heat, and light. Electricity as a substitute for gas is not a delusion; it is practicable. It supplies a real want; but for domestic purposes it is at present a luxury, and an expensive one. Predictions as to its grand future have not yet been fulfilled. The public have shown themselves remarkably sensitive to its influence on gas. Nevertheless, it has a bright future before it, and, though the poet might have said—

"It was a phantom of delight,  
When first it beamed upon my sight;  
A lovely apparition sent  
To be a moment's ornament."

—if he had lived in the present day, he would have considerably added to the period in which he estimated the electric light to be an ornament.

## DISCUSSION.

The Chairman, in moving a vote of thanks to Mr. Preece for his valuable paper, said that gentleman had passed the whole subject of electric lighting in review, in a manner which must have struck home to the minds even of those among the audience who had not before given particular attention to the subject. He had followed the energy pent up in the coal in former ages through its transformations in the steam-engine and the dynamo-machine, where it was manifested as an electric current, passing through the conductor into the lamp regulator, where, through the resistance offered to its passage, heat was again generated, being the very form of energy with which they started, with the difference, however, that the heat produced in the electrodes of the lamp was of a much more intensified nature than the heat developed by the combustion of the coal. Hence, after all, electric lighting meant nothing else but carrying energy from the coal to the carbon in the lamp. But simple as the problem appeared when thus put, it had required the combined ingenuity and labour of philosophers and of practical electricians, extending not indeed over centuries but over decades; and even now a point had only been arrived at where it could be said that electric lighting was feasible. At the present day, advances were made more rapidly than had ever been the case before, and before long it might be possible to say that electric lighting was an accomplished fact. The great experiment soon to be made in the City of London would be an event of the greatest importance, and the greatest city in the world was now leading the way in utilising this new agency in a way which would leave no doubt as to its efficacy. Photometry, the sub-division of the electric light, and various applications of electricity, had also been touched upon in the paper, and though most of the propositions put forward in it would be accepted by all who understood the subject as natural facts, still, naturally enough, in so new a science, there were other points which were controvertible, and which he (the Chairman) would like to argue with Mr. Preece, but that he feared to try the patience of the meeting. They had sometimes argued questions very strongly, but had always been very good friends afterwards. If he had understood aright, Mr. Preece hoped, and great philosophers had entertained the same hope, that the divided light would ultimately equal the centralised light in economy. He begged to differ from that conclusion. Divided light meant light brought nearer to the eye, and the eye could not bear a light of such intensity in close proximity as it could bear at a distance. Mr. Preece had very well said that light was nothing but heat of the intensest kind. In order to have the greater number of light rays over heat rays emanating from a centre, it was necessary that the temperature should be raised to the utmost attainable point; even in the

electric arc, then burning in the lamp before them, probably nine-tenths of the rays emanating from that centre were not luminous, but heat rays, otherwise, even with the lamp so far removed, they would not be able to heat the light. Although he believed that divided lights would be very largely used, and with great effect, where centralised light was not applicable, yet it might well be argued from *a priori* reasoning that a central light must be always more economical than a divided light. With regard to his own experiments, mentioned by Mr. Proce, he had carried them on since last year for the purpose of promoting the growth of plants by the electric arc, with the object, not so much of ripening strawberries and cucumbers sooner than his neighbours, but of ascertaining to what extent it was possible to produce rays capable of acting in substitution for solar rays, and also to what extent plants could be accustomed to bear this agency without intermission. He hoped to be able to lay further results before the scientific societies before long. One point of interest was the fact, that the steam-engine he employed to produce the electric light at night, afterwards yielded, through condensation of the waste steam, the heat for the green-houses, so that the electric light did not add materially to his coal consumption. Having to keep a fire under the boiler day and night, he thought it a good opportunity for utilising the steam power during the daytime, and he had done so by means of leading wires from the dynamo machine, to another similar machine at the farmstead working a chaff-cutter, to another for working a pumping engine nearly half a mile distant, and to a saw-bench in another direction, so that while doing its work near the green-houses, the engine was also cutting chaff and wood in one direction, and pumping water in another, and he hoped yet to make it available for ploughing the land also. These facts showed that this mode of energy was extremely pliable, and could with great ease be made available at a distance. It is also important to remark that no other electrician was employed to keep the apparatus in order than the head gardener, without certainly any special training for this work.

Mr. Cromwell Varley, F.R.S., had not paid much attention hitherto to the application of the electric light, and the very full remarks already made left him very little indeed to say. The reason why lights placed one after the other in one circuit were not so economical as the concentration of the entire power in one lamp placed at a great elevation, was that a considerable amount of power was required to heat the carbon sufficiently to make it glow, and that power was all dead loss. Every particle of power employed beyond that amount would heat the carbon more and more, and so a greater amount of heat would be obtained when the entire energy was concentrated in one lamp and one carbon, and a much greater incandescence than when so much power was spent in heating, at different parts, a great number of lamps. If it were possible to have stretched along a street one long conductor of fine wire of such a character that it would bear a very much greater heat than carbon, and could be made incandescent, of course the most uniform and perfect light would be obtained. Failing that, the next best thing was to get a comparative equality by using one light at a greater elevation. But in the City of London, where the atmosphere was loaded with particles of carbon which practically acted in such a way as to reduce the light from white to red, he was afraid that this mode of illumination would be no more successful than that of the sun on a foggy day.

Mr. Swan remarked that Mr. Proce had expressed some doubt as to the economy of light produced on the principle of the incandescence of a very thin conductor of carbon, apparently grounding his opinion upon Sir William Armstrong's calculations, but if the figures given by Sir W. Armstrong were worked out, they would show that

the light obtained by means of the incandescent lamp be divided to any extent into small portions, might be conducted to any place where it was particularly wanted, and considering the advantage of distributed light, even taking the figures of Sir William Armstrong, it could be obtained with a sufficient economy for practical purposes. And first Sir William Armstrong's experiments were much greater degree of economy had been run might say, without fear of contradiction, that twice the amount of light could be obtained by expenditure of power; it would be fairly a mark to say that a light of 350 candles could be obtained by an expenditure of one horse-power, considering how very small a quantity of power required to develop the mechanical force would be sufficient—a very satisfactory amount of distributed or divided light was afforded by Varley's illustration of the ideal mode of distributing the light along a street, namely, by having a wire made incandescent throughout its entire length, had suggested to his mind a very strong argument in favour of the divisibility of the electric light principle of incandescence, for it appeared so evident that it would require no more power, and would, therefore, cost no more, to extend the length of a street, than it was the same wire if it was cut into a number of segments separated by means of conductors of a size to absorb any very large amount of the power. Varley's straight wire was cut up into four pieces, the same power would evidently be required to produce the light, and the economy of the principle of incandescence, appeared to be, self-evident.

Sir Charles Bright called attention to advances made in electric lighting over since the Exhibition, and especially in the improvements made in several of the dynamo-electric lamps. Great improvements had also been made in the kinds of arc and incandescent lights which had been introduced. Mr. Proce had calculated from the cost of coal, which was the common unit in making power expenditure, but he hoped the day would come when calculations of the cost of the electric light would not be entirely based upon the consumption of combustible material. When the system was properly organised, the power necessary for the electric light might be derived from the watersheds of the country, so the cost of the light, at all events, would be within reach of such power, would be reduced much in comparison with the cost of coal. The cost of tides and of waterfalls might be hereafter calculated for producing light for the whole country, the expenditure of one pound of coal, and in obtaining light during the night, but for most of power for daily application.

Mr. Phillips (nephew of Mr. Brush) gave a brief of the progress of the electric light in America since the course of the last two years, about 8,000 lights had been introduced there, many of the best illumination in factories and depôts. The lighting of streets and open spaces in that country had been very widely adopted. At Wabash, in Indiana, the whole town was completely illuminated by four lights, placed on the dome of the Court-house, yielding a better illumination than could be obtained more than five times the expenditure in gas light the time could be distinguished upon half a mile distance, and within a radius of 400 feet the smallest print used in newspapers distinctly read. These four lights required 1 power, and were maintained at a cost, including the investment, of not more than 1,100 dollars little over £200 per annum. In New York was to be extended over an area of a square

lights would be thereby introduced for street illumination. The Montreal Docks were illuminated by 17 incandescents of 17,000 feet of wire, and operated by a dynamo-electric machine, absorbing seventeen horse-power. Various factories in the docks were also lit in the same way; and as £500 had been invested by more than electric light apparatus. Upon that investment about £300 per annum was being saved it of gas, so that in a little over a year, the apparatus would be paid for in the money five times greater volume of light, and one all the colours of the goods to be distinguished without vitiation of the atmosphere in the docks, which was, of course, a matter of very great importance. Wabash contained 5,000 inhabitants over a radius of about five furlongs. A light threw shadows of some density, he experience of perfectly unprejudiced men in the shadows the light was considered, in fact, much more than could be found from two ordinary street gas-lamps.

Mr. Swan, in reply to Mr. Preece's remark that a power could, with difficulty, be realised from the fact that, by one of Dr. Siemens's 6,000 power candle-light, elevated 60 feet from the ground, a *Globe* newspaper could be read at a distance of 80 yards, and much more than under a gas-jet 15 feet above the ground. Such lights were peculiarly valuable for docks and other large areas, as watchers could perceive any tampering with the goods at a distance of 400 feet. Probably the light was a more economical than gas, and, indeed, of gas-jets necessary to properly light the docks could hardly be calculated. The lights on the Thames Embankment threw out highly refrangible rays, soon visible in fog, but that was not the case with the gas-jets then burning in the docks. The highly refrangible rays given out by the incandescents ceased to pass through a fog, the rays from the incandescent carbon points would be visible at considerable distance. From experiments, that a powerful light, 80 feet high, would, in dense fog, give a good light 60 or 80 ft.

Mr. Swan, in reply, said the difference between the light of the incandescents and the gas-jets was but small, and one merely in intensity. He agreed with Dr. Siemens, that there was no when the problem regarding distributed light, and where it was more economical and centralised light. He might take exception to the remarks of Mr. Varley and Mr. Swan, as he thought it was not even theoretically possible to have a wire in a state of incandescence along its whole length if it were practicable to do so, it would be able to divide the wire into a number of segments, but while it was found to be impossible to keep 80 or 40 of these lights going, it was equally impossible to maintain a wire in incandescence that would illuminate a distance of 40 yards long. At present the idea of the light by breaking it up into small jets was quite out of the question. Mr. Swan's remarks on the two occasions he had visited London were apart—in raising the illuminating power from 140 to 250 candles, showed the progress was making, and that he was working in the right direction. Mr. Phillips's account of what had been done in the town of Wabash and elsewhere in the State was extremely interesting, but the town was so small and it would be long before we should be able to put our present apparatus, to produce a light of the same intensity as the light of St. Paul's, would do much more

than illuminate the immediate neighbourhood of the cathedral. He concluded by requesting the meeting to join in a cordial vote of thanks to Mr. Stevens, of Basingstoke, Mr. Hendricks, Mr. Joel, Mr. Swan, Mr. Crompton, Messrs. Siemens and Co., the British Electric Light Co., and several other gentlemen and companies who had kindly furnished lamps, diagrams, and apparatus for the purpose of the lecture.

The meeting was then adjourned.

During the first part of the meeting, the room was illuminated by a Siemens lamp and several Joel lamps. During the latter part it was lighted by a number of Swan lamps and a Brookie lamp. The current was supplied by a large and an ordinary-sized Gramme machine, and by a Birgin machine. These machines were driven by the Robey 10 h.p. engine which has been used during the past fortnight for the illustrations for Professor Adams's lectures and Professor Perry's paper. The Society is indebted to the proprietors of the above lamps, machines, and engines, for the loan of them.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday, March 24, 1881; LATIMER CLARK, F.R.G.S., in the chair.

The paper read was on "The Future Development of Electrical Appliances," by Prof. JOHN PERRY. The paper will be printed in a future number of the *Journal*.

#### MEETINGS OF THE SOCIETY.

##### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

APRIL 6.—"The Discrimination and Artistic Use of Precious Stones." By Professor A. H. CHURCH, F.C.S. Sir PHILIP CUNLIFF-OWEN, K.C.M.G., C.B., C.I.E., will preside.

APRIL 27.—"Five Years' Experience of the Working of the Trade Marks' Registration Acts." By EDWARD JOHNSON.

MAY 4.—"Buying and Selling; its Nature and its Tools." By Professor BOWMAN PRIOR, M.A. Lord ALBERT S. CROMBIE will preside.

##### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

APRIL 6.—"Canada; the Old Colony and the New Dominion." By E. HARTLEY HALL. JOHN RAE, M.D., F.R.S., will preside.

MAY 10.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGAERTH.

#### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

APRIL 28.—"Impurities in Water, and their Influence upon its Domestic Utility." By G. STILLINGFLEET JOHNSON, F.C.S.

MAY 12.—"Recent Progress in the Manufacture and Applications of Steel." By Prof. A. K. HUNTINGTON.

MAY 26.—"Telegraphic Photography." By SHEPHERD BIRWELL. Prof. W. G. ADAMS, F.R.S., will preside.

##### INDIAN SECTION.

Friday evenings, at eight o'clock:—

APRIL 29.—"On Indian Building Acts." By General MACLAGAN, R.E.

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.O.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CAMBRIDGE LECTURES.

Monday evenings, at eight o'clock:—

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Four Lectures.

## Syllabus of the Course.

## LECTURE I.—APRIL 4.

Introduction. Early forms of twisted, plaited, and looped threads. Ornamental borders of Assyrian, Greek, Roman, and other costumes. Sumptuary laws. Venetian books of patterns for embroidery and lace. Flanders a centre of linen trade of Europe. Spanish and French importations of early lace. Effect of production of machine-made lace upon production of hand-made lace.

## LECTURE II.—APRIL 11.

Needlework upon a material. Needlework upon separate threads. Venetian needle-point lace. Needle-point and tape lace. French needle-point lace-making centres. English and Flemish needle-point lace.

## LECTURE III.—MAY 2.

Fringes. Twisted thread-work in England in the 15th century. Early designs for plaited and twisted threads. Italian, Flemish, French, and English pillow lace. Laces of primitive design.

## LECTURE IV.—MAY 9.

Resumé as to styles of design in hand-made lace. Traditional patterns. Sketch of the development of inventions for knitting and weaving threads to imitate lace. Differences between machine and hand-made laces. Modern hand-made laces at Burano, Bruges, Honiton, &c.

This course will be illustrated by specimens of lace. Diagrams and photographs enlarged will be shown by means of the lantern and oxyhydrogen light.

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRIDGEMAN CARTER, F.R.C.S. Three Lectures.

May 18, 23, 30.

## MEETINGS FOR THE ENSUING WEEK.

- MONDAY, APRIL 4TH ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Lecture I.) Mr. Alan S. Cole, "The Art of Lace-making." (Lecture I.)  
Farmers' Club, Inns of Court Hotel, Holborn, W.C., 4 p.m. Mr. T. Bell, "The Agricultural Returns for 1880, and their Teaching."  
Royal Institution, Albemarle-street, W., 8 p.m. General Monthly Meeting.  
Society of Engineers, 4, Westminster-chambers, 7½ p.m. Mr. Perry F. Nursery, "Illumination by Means of Compressed Gas."  
Medical, 11, Chandos-street, W., 8½ p.m.  
Victoria Institute, 7, Adelphi-terrace, W.C., 8 p.m. Prof. Ralfour Stewart, "The Visible Universe."  
TUESDAY, APRIL 5TH ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. E. Hepple Hall, "Canada; the Old Colony and the New Dominion."  
Royal Institution, Albemarle-street, W., 8 p.m. Prof. K. A. Schöffer, "The Blood." (Lecture XII.)  
Central Chamber of Agriculture (at the House of the Society of Arts), 11 a.m.  
Civil Engineers, 23, Great George-street, Westminster, S.W., 8 p.m. Mr. B. Baker, "The Actual Latent Pressure of Earthwork."  
Pathological, 53, Berners-street, Oxford-street, W., 8½ p.m.  
Biblical Archaeology, 9, Conduit-street, W., 8 p.m. 1. Mr. Ernst de Bunsen, "The Times of Israel's Servitude and Sojourning in Egypt." 2. Prof. Ed. Schrader, "Abydos and the Book of Daniel."  
Zoological, 11, Hanover-square, W., 8½ p.m.  
WEDNESDAY, APRIL 6TH ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor A. H. Church, "The Discrimination and Artistic Use of Precious Stones."  
Geological, Burlington-house, W., 8 p.m. 1. Mr. Frank Butler, "The Microscopic Structure of Devitrified Rocks from Bedgellert and Snowdon." 2. Mr. Frank Butler, "The Microscopic Characters of the Vitreous Rocks of Montana, U.S." 3. Mr. T. Mellard Reade, "The Date of the Last Change of Level in Lancashire."

Entomological, 11, Chandos-street, W., 1  
Pharmaceutical, 17, Bloomsbury-square  
Mr. A. W. Gerrard, "Wandja," a new  
Poison, its Composition and Properties  
Royal College of Physicians, Pall-mall E  
(Lancian Lectures.) Dr. Southey, "1  
(Lecture II.)

Archæological Association, 22, Beakville-  
1. Mr. Thomas Morgan, "Remarks  
Monks at Brading." 2. Mr. J. T. Ivis  
Cathedral of Bath, discovered during  
1880."

Obstetrical, 53, Berners-street, Oxford-  
Institution of Naval Architects (at the  
SOCIETY OF ARTS), 12 noon. 1.  
2. Election of Officers and Council. 3.  
President. 4. Mr. J. D'A. Ramsay,  
Buenos Aires, Argentine, caused Corvete, at  
Steel Hulls and Steel-faced Armour  
Ships." 5. Mr. W. Parker, "On  
Behaviour of Steel used in Boilers,  
Yacht Livadia." 6. Mr. J. R. Ravenel  
creating use of Steel for Shipbuilding  
Engineering."

THURSDAY, APRIL 7TH ... Institution of Naval &  
HOUSE OF THE SOCIETY OF ARTS, 12  
W. H. White, "The Stability of  
Ships." 2. Mr. James Hamilton,  
Paddle Steamers, and their Position  
Wheels." 3. M. Marc. Berrier, For  
of Mild Steel for Shipbuilding in 1  
yards." 7 p.m. 1. Mr. W. Denny,  
cation in Naval Architecture." 2. 1  
"Crank Shafts." 3. Mr. C. Strome  
of the Cut Off and Length of Stroke  
of Steam Engines."

Royal, Burlington-house, W., 4½ p.m.  
Antiquaries, Burlington-house, W., 8½ p.m.  
Linnean, Burlington-house, W., 8 p.m.  
Cobbold, "The Parasites of Elephant  
The Indian Species of Primula.  
Sorby, "The Green Colouring of the  
4. Dr. W. A. Hardman, "Individual  
Bronchial Eac of Aurochans."

Chemical, Burlington-house, W., 8 p.m.  
Society for the Encouragement of Fine  
street, W., 8 p.m. The Second Conv  
South London Photographic (at the  
SOCIETY OF ARTS), 8 p.m.

Royal Institution, Albemarle-street, W.  
Statham, "Ornament Historically as  
sidered." (Lecture IV.)

Inventors' Institute, 4, St. Martin's-place  
Civil and Mechanical Engineers, 7, West  
S.W., 7 p.m. Mr. B. Haughton, "E  
Archæological Institute, 16, New Buri  
4 p.m.

FRIDAY, APRIL 8TH ... Institution of Naval &  
HOUSE OF THE SOCIETY OF ARTS, 12  
H. White, "The Rolling of Rolling 3  
E. Froude, "The Landing Phenom-  
making Resistance of Ships." 3. M.  
Freeboard and Displacement in Rel  
Ships among Waves." 7 p.m. 1. C  
The Imperial Russian Yacht Levee  
Beed, "The Injuries Sustained by t  
Bay of Biscay." 3. Mr. J. Biles  
Deduced from Curves of Resistance.  
Hall, "Notes on Screw Propulsion  
Archer, "Shipbuilding a Thousand 1  
Royal United Service Institution, White  
Captain J. C. B. Colomb, "The Ne  
Intelligence Department."

Visit to British Museum (Natural  
Kensington, under the direction of  
ward.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,481. Vol. XXIX.

FRIDAY, APRIL 8, 1881.

*Communications for the Society should be addressed to the Secretary  
John Street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

The lecture of the fourth course was delivered Monday, 4th inst., by ALAN S. COLE, "Art of Lace-making." Enlarged photographs of various kinds of lace alluded to in the lecture were shown by means of the lantern and gas light.

Slides will be printed in the *Journal* during a recess.

## DOMESTIC ECONOMY CONGRESS.

The next meeting of the General Committee of the Society of Arts on Wednesday, 6th inst., the following ladies attended:—The Countess of Airlie, Viscountess of Leeds, the Countess of Airlie, Viscountess of Leeds, Lady Arthur Russell, Dowager Lady Alderley, Lady Jane Stewart, Lady E. Kennedy, Lady Beay, Hon. Mrs. Sydney Cole and Miss Cole, Lady Verney, Bayley, Miss Rose Adams, Mrs. Bartley, Mrs. Buckton, Mrs. Burke, Mrs. Cotton, Mrs. Grenfell, Miss Mary Frances Martin, Miss H. A. Martin, Miss Otiswoode, and Miss R. Spottiswoode, Webb, Secretary of the Congress. Lord Cromwell, Sir Henry Cole, K.C.B., Major-General, R.E. O.S.I., and the Rev. Newton, members of the Executive Committee, were present.

## HOUSE SANITATION.

The Society will offer the following Medals for the best Sanitary Arrangements in Houses built in London, the plans of such arrangements to be deposited in the Society's Rooms, Adelphi, in London, and to be sent in on or before 12th inst.:

**Silver Medal** for the best sanitary arrangements laid out and in satisfactory working, in tenements or in houses let out in tenements to artisans, for which the yearly rental is paid.

**Silver Medal** for the best sanitary arrangements in actual working, in a house of the

yearly rental of £40, or less, to about £200 in value.

3. One Silver Medal for the best sanitary arrangements, in actual satisfactory working, in a house of the yearly rental value of £200 and upwards, to any amount.

4. The houses must be open to the inspection of the Judges, who, in considering their award, will be guided by the suggestions of plans for main sewerage, drainage, and water supply, made under the Public Health Act, 1875. The houses must have been in actual occupation within the last three months, and a Certificate must be given by the occupiers, on a printed form, stating the satisfactory working of all the sanitary arrangements, such form to be obtained at the Society of Arts.

5. The houses may be old, fitted with modern sanitary arrangements, or may be new. They must be within the metropolitan area of the Board of Works.

6. The sanitary arrangements must include the conditions for good water supply, drainage, warming, and ventilation of the house, and precautions taken against frost.

7. The medals may be awarded to the occupiers of the houses, or the lessees, or the owners.

8. The plans must consist of a ground plan and sections, to the scale of not less than one inch to five feet; details of not less than one inch to the foot. The plans may be accompanied by specifications.

9. The names of the architects, surveyors, or sanitary engineers who directed the sanitary arrangements should be given, and Certificates will be awarded to those whose plans obtain the Medals.

## PROCEEDINGS OF THE SOCIETY.

## EIGHTEENTH ORDINARY MEETING.

Wednesday, April 6th, 1881; Sir PHILIP CUNLIFFE-OWEN, K.C.M.G., C.B., C.I.E., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Beattie, William, London and South Western Railway Works, Nine-elms, S.W.

Cockburn, James, 11, Heathcote-street, Mecklenburgh-square, W.C.

Crossley, John Thomas, Q.C., 91, Cheyne-walk, S.W.; 4, New-square, W.C.; and Junior Athenaeum Club, S.W.

Gibson, Joseph F., Clavelly, Woodchurch-road, West Hampstead, N.W.

Goodwin, Thomas, 12, Southwark-street, S.E.; Law, James, 544, Oxford-street, W.

Lovett, William John, Carver-street Works, Birmingham.  
 Lyell, Francis Horner, F.R.G.S., Nettlestone, Widmore, Bickley, Kent.  
 MacGregor, Alexander, M.A., 6, Charles-street, Berkeley-square, W.  
 Powell, Frederick, F.R.G.S., Bakewell, Derbyshire.  
 Pupikofor, Oscar, The College, Matlock, Derbyshire.  
 Stabbs, William Henry, 3, Winton-square, Stoke-on-Trent.

The following candidates were balloted for, and duly elected members of the Society:—

Atkinson, John, Tosti, Falsgrave, Scarborough.  
 Bacon, George Washington, F.R.G.S., 127, Strand, W.C.  
 Black, William, South Shields.  
 Lorimer, William, Messrs. Dubs and Co., Glasgow.  
 Russell, William J., Ph.D., F.R.S., 34, Upper Hamilton-terrace, N.W.

The paper read was—

### THE DISCRIMINATION AND ARTISTIC USE OF PRECIOUS STONES.

By Professor A. H. Church, F.C.S.

It was not without set purpose that I associated a scientific and an artistic conception in the title of this paper, for I am desirous of making a contribution, though it be but a small one, to the intelligent study and intelligent employment of precious stones. And I am convinced that some acquaintance with the less obvious qualities of well known gem-stones, and with the distinguishing characteristics of those species which remain practically unrecognised and unappreciated, will help forward the improvement of the jeweller's art in this country. Most admirable and pleasant colour-combinations are attainable by the aid of materials which, in many cases, are now by no means costly. Curious and delicate hues, of luminous quality, and in enduring substance, may be arranged and grouped in forms of endless beauty and variety. Neither silks nor paints, nor even enamels, can ever equal the colours of precious stones in durability, or in brilliancy and pulsating variety of hue. By pointing out some of the methods of discriminating one stone from another, I hope to be able to explain the modes which I shall cite or suggest, for their artistic employment. But I hope to do more than this. For when we know something about the intimate nature of any art-material, we begin to feel a more intelligent and a more lively interest in examples of good workmanship wrought in the substance in question. Every *connoisseur* or collector of artistic objects must have shared in experiences of this kind. He may have been once quite dead to the peculiar merits of certain works—say, in bronze, not even glancing at any specimens falling in his way. Then some casual circumstance, perhaps an exciting contest for a fine piece of work at a sale between two enthusiastic collectors, or perhaps the gift of a choice specimen, may have drawn attention, I will not say to the merits of such specimens, but at least to the esteem in which they may be held. Curiosity—it may be an intelligent curiosity—is excited. Investigation, more or less searching, follows. The hardness of the metal, its *provenance*, its designer, its age, the mode of

manufacture, whether by casting or hammering, the manner of decoration, whether by engraving, or inlaying; the colour, the texture of the surface, the presence or absence of *patina*, and not a few other points of interest, constitute the materials of study. Study provokes observation, and observation provokes study, so that before long the group of artistic bronzes exerts a kind of fascination upon the new votary. If his knowledge is superficial and inaccurate, or if he be an amateur or collector just because it is a fashionable pursuit to gather together or to admire classes of artistic objects, well, then, he really knows what and why he admires. It delights him just as much as genuine works, as he is not sure that they are forgeries; has not sufficient patience for the mastery of sufficient insight into the characteristics of productions, to discriminate them from the false. It often happens thus with the study of precious stones. He knows nothing of the elements, say, of surface lustre, and the elements which go to make up the *tout ensemble* of a particular gem, and is quite satisfied with a bit of paste, or a cleverly contrived imitation. No doubt, in some cases, even an keenness of vision does not suffice to distinguish the true stone from the false, although the durability of the genuine specimens ultimately prove their superiority. But it is difficult to learn to appreciate the peculiar essential characters of the majority of the precious stones. What I wish to accomplish, has, then, not merely relation to the use and arrangement of gems, but also to appreciation of their inherent characteristics at least as these affect their appearance. I wish to sketch these characteristics, and then to pose them into pictures. For this purpose I set down, in some sort of order, the most important optical distinctions belonging to precious stones, arranging these under the general heads "Surface" and "Substance":—

1. Plane .....	FORM ..	}	SURFACE ..
2. Curved .....			
3. Metallic .....	LUSTRE ..	}	SUBSTANCE ..
4. Adamantine .....			
5. Resinous .....			
6. Vitreous .....

I will now proceed to give some examples of use of such a tabular statement as this. When we are dealing with the shape of stones, we note the boundaries are either plane or curved. Now we want to use curved surfaces, like those of which we shall find that it will not answer to a

other curved surfaces, like those of the moonstone; and especially is this the case the size of the stone as well as the of the curved surface is nearly identical; the result will be attained by combining stones with one having a curved surface, citing an example from the series of expressing qualities of surface, it would that gems having an adamantine sort better with those which present brilliant surface known as waxy, do with those which show a nearer to the adamantine surface, and which are resinous. The diamond and the jargoon prove or bring out each other's qualities, we too many points in common; but the records well with the pearl, and the jargoon the turquoise, that is, the adamantine nearly, and the resinous with the waxy. Now, into the substance of stones, rather than their surface, their relations to the trans-colourless light furnish many illustrations and unwise, or effective and defective ones. For example, chatoyant stones, like do not associate well with translucent the chrysoprase and the chalcodony—opacity of the latter confuses, because it too closely the chatoyancy of the most transparent stones accord well with those which interrupt the passage of light by such internal reflections. The result on this account, combines admirably with the pearl, but it affords too strong especially when of large size, with the pearl to associate pleasantly with this nearly is. From amongst the qualities pertaining to the colour of stones, examples of the following table may be cited. When a stone "fires" in it—that is, when its refractive index actions upon light are high—and chromatic hues, then it looks best if with gems in which this property is included. Again, monochroic stones, which transmit beams of the same colour, associated with pleochroic stones which show two or more hues, while the latter should be kept together.

useful, as an introduction to the study of precious stones, to say a few words of the physical experiments by aid of which their qualities can be best ascertained and distinguished—where, in fact, we cannot employ our eyes alone to the eye. The materials required for the experiments are very simple, and include—first, of mineral fragments—diamond, topaz, pinel, chrysoberyl, topaz, garnet, and others to be used as tests for relative hardness. A pocket spectroscope, by which absorbances of those of the garnet and jargoon, are noted.

A spectroscope, or double image prism, suited, by which the pleochroism, or difference in the light transmitting in different directions in the same stone, may be ascertained. In the case of easily fusible solids, of high specific gravity, or 2·3 upwards, by means of which the different densities in doubtful specimens are easily accomplished.

indications of this critical apparatus to the solution of certain precious stones will be

mentioned further on, in connection with particular species. But a few lists or tables of the hardness, pleochroism, and specific gravity of some of the more interesting and valuable of precious stones will be useful here. Such tables are more convenient for practical and ready use when arranged in a kind of progressive order, such as I have adopted. The hardness assigned to the different species, or varieties, must be taken as average or approximate only. The terms used to designate the differing colours of the oppositely polarised beams in dichroic stones, are the best I could select, but refer merely to the specimens examined. The table of specific gravities contains a selection from about 200 specific gravities, taken by myself with unusual precautions.

It has been no easy matter to decide upon the order in which the several most important precious stones should be discussed. In a chemical paper, a classification in accordance with composition would be absolutely right; while such physical properties as hardness and specific gravity might be made prominent features in the arrangement of the species in a physical paper. But as the ornamental or artistic employment of precious stones conveys primarily, if not wholly and ultimately, an appeal to the eye, it is clear that such optical properties as can be comprised in the terms colour, lustre, and light should afford the bases of our classification. On the whole, the prominent feature of precious stones is their colour, and the easiest way of considering their colour is to adopt the order of succession of the colours in the ordinary rainbow or prismatic spectrum, beginning with the white light from which they all spring.

*White Stones.*—The diamond naturally takes the first position if we consider its hardness, its remarkable composition, and its strong refraction and dispersion of light. Its properties, so far as they appeal to the eye, differ much from those belonging to the majority of other stones, and it forms, partly in consequence of this peculiarity, as good a border or setting to other jewels as a gold frame does to a picture. Of course much depends upon the quality of the diamond, and much upon the shape which is given to it by the lapidary. The flat plates of *lasque* diamonds, and, in less degree, the step-cut stones with broad tables, exhibit the unique and splendid lustre which is peculiar to the polished surface of this stone; these forms also permit the transparency and the total internal reflection of light to be well seen. Even the form of the diamond crystal, the regular octohedron, when its surfaces are really planes, well exhibits the transparency and reflection of the stone.

This seems the place to raise a protest, which, indeed, I have done on many previous occasions, against the ignorance and narrowness which would condemn diamonds and all other stones, irrespective of all the optical differences which they present, to be cut *en cabochon*, or tallow-topped, that is, with a convex rounded surface. A certain clique of artists and amateur writers on art insist upon all stones being cut in this way, which, in the majority of cases, is fatal to the development of those optical qualities upon which the beauty of precious stones mainly depends. Indeed, the faceting of the great majority of transparent stones is not only a necessary operation, but it should be done in strict accordance with certain rules of proportion, which may be deduced from the optical constants of the species of stone operated upon. But with pale and defective specimens, the *cabochon* form is often found more suitable than the rose, or brilliant, or stepcut; and it is the only method of showing to advantage the peculiar beauties of a large number of translucent, chatoyant, or opaque stones, like the chrysoprase, the opal, the moonstone, and the cat's-eye.

Next to the diamond, we may place the colour-

less zircon or jargoon, then the pale the white sapphire, the white topaz, beryl. Rock crystal will come below point of beauty and brilliancy. Zircon (of which a fine specimen set be seen in the British Museum Museum now at South Kensington) approach prismatic brilliancy to a diamond especially, does the rare and curious kite. There is, however, always a set in finding an appropriate use for lustrous stones in any article of jew for personal adornment. The more prismatic they are—the more they diamond in fact—the less available a usual purpose to which gems are put are peculiar qualities in these stones not be lost to artistic employment stones in question were judiciously materials which would prevent the taken for diamonds. A white diamond or never be bordered by green to these stones would form an agreeable with a white zircon, a phenakite, or In the sapphire there is usually picion of milkiness, and in the a cool greyish tint, which prevent from resembling the diamond to be taken for imitations of the many of these colourless stones, not and rock-crystal, in all probabi appropriately used when set as be and other large pieces of metal-work in the form of plaques for engravi It is scarcely necessary to justify these minerals, and this is not the upon the question, particularly as rather wide use of the term pre able to include these materials, and which I shall have to speak pre precious stones. Of two other v employed in jewellery, the moon pearl, a few words may be in The moonstone forms an excell in many combinations for the does not associate quite so well with the diamond. With deephthysts, spinels, and tourmalines, gems look more refined than the these stones, which fetch a shilling only, should always be accurate highly re-polished before being use are too irregular, and their surface as imported from Ceylon, to show light sheen with half its intensity, passed again under a careful lapid improvement thus effected is marvel of the pearl, whether its "orient" be prismatic hues, or whether it be white merely, is too well known to named in this connection. But I m to say one word in deprecation of t expenditure of time, of ingenuity, materials, which the attempt to conv lar pearls into structures resembling often caused. The result is nearl unhappy.

*Red Stones.*—The ruby may fitly before other coloured stones. sapphire, and all the transparen

ne, ranks next to the diamond in hardness, is, moreover, a stone of great beauty. By the experts in jewels are right in assigning the highest value to those rubies which have a "pigeon's blood" colour—this is the true hue. But the paler colours, and those which range upon pink and crimson, and even those capable of being so treated by means of a white and black enamel, or with a green, like olive-green tourmalines, as to make them resemble the production of very beautiful effects. The great mistake commonly made in the treatment of the paler rubies, is to attempt to treat them in the same way as the deeper-coloured stones.

It is difficult to describe the peculiar colour of the ruby in words. In fact, our nomenclature of colours is neither ample nor accurate. The perception of delicate differences between the hues is growing, but the language by which we attempt to describe the hues which we have to appreciate is either stationary, or else reductions from time to time of unsatisfactory words, derived from the caprices of French

The time has really arrived when a series of hues of all sorts should be carefully and appropriately named; but, in the case of the ruby, the question of pleochroism comes in, and the difficulty of describing the colour of this stone greater. There is also some "fire" in the stone, and much internal reflection of light, while its surface lustre lies between the sinuous and vitreous. These four properties—the red of the ruby, a peculiar lustre, the two other species of precious stones, the spinel and the garnet—which come in different colours, do not equally possess. The high make up the colour transmitted by the stone does not differ much, but yet they help to properly cut stone, a delicate variation which is not present in any other red stone, imitative substance. The dichroscope, however, never fails to discriminate between a ruby on one hand and a spinel or a garnet on the other.

The two latter stones are, of course, the ruby, and the former is always lighter, of less specific gravity. For the whole of the corundum family of which the specific gravity of 4, and a hardness is nearly, and in some cases quite 9, on the Mohs' scale.

One of the happiest uses of the ruby is in the inlay, in certain gold vessels of Indian origin. The external surface of these vessels is covered with a system of interlacing ridges and furrows. The rubies, generally small, oval, and round, are set along the furrows. Thus they are protected from the chance of dislodgement, and the effect they produce, of a rich deep crimson over which a gold netting has been laid in perfect harmony with the materials and workmanship. For, naturally, the metal is pure, or nearly pure, throws a ruddy light which is reflected from surface to surface; the interior of gilt vessels. The same thing is seen in the golden furrows of which we have seen the rubies seem to rest in a golden hue in which the yellow, and orange, and red, now one and now another, appear to the gold should not be burnished where

much contrast between the metallic surfaces and the rubies is desired, but the stones themselves should be as brightly polished as possible, in order not only to develop the full beauty and variety of their colour, but also the very considerable surface lustre which the rubies possess. There is another kind of Indian jewellers' work to which most of the remarks I have just made apply. A perforated plate or disc of delicate arabesque or radiated work is found decorated with ruby beads, round or oval, attached to the circumference of the ornament, or else introduced into its midst in concentric circles. Here dull, dead or "matt" gold is particularly appropriate, as affording a pleasant contrast to the rich, smooth, and soft transparency of the rubies, which, from the manner of their mounting, may be looked through. The refinement of the slender gold-work, which, in this class of jewellery, approaches the delicacy of filigree, sets off by its minuteness of detail the simpler and bolder forms of the plain, smooth, rounded stones, which give it colour and warmth. I must dwell for a moment or two upon another Eastern method of dealing with the ruby. I refer to the use of this stone as an inlay or onlay—that is, an incrustation—upon jade, both white and green. It is not so much here a beautiful contrast of colour that is attained, although the greenish grey or olive green of the jade, enhances the redness of the ruby; but it is a contrast of textures, a contrast of surfaces, a contrast of translucencies. You see but a little way into the jade, though it is illuminated by a soft diffused light; but you see through the clear deep-toned rubies, with their flashing beams of crimson.

Now compare with these examples of the artistic employment of the ruby, the ordinary mode in which this stone is set by English jewellers. Look at the half-hoop ruby ring, with five rubies well matched in colour, and graduated exactly in size, set close together in a regular row. You see, perhaps, a little speck of gold appearing here and there at each end of each stone, but nothing is made of these pieces of gold. You accept them because you know they are necessary to hold the stones in their places, but you find neither invention nor beauty in these little bits of gold claws. In fact, they are frequently prepared by the gross, ready for the mounting of any stones, provided the shape of the latter be suitable. Rubies, sapphires, diamonds, garnets, and emeralds are all set in the same way, not an attempt being made to adapt the amount of gold surface or its form to the specific nature of each gem. But why should not some variety and some appropriateness of mounting be secured for all stones? How exquisite, and yet how strong, were the gold and enamel settings of precious stones in the Cinquecento time in Italy. Let those patrons who desire the rather barbaric splendour of masses of rubies gratify their taste by means of jewels in which the setting is not seen at all. But surely a fine stone is worthy of a fine and originally designed setting—proportioning the latter in form, in amount of work and surface, and also in colour, whether red, or green, or yellow gold, or enamel, to the shape and the hue of the stone to be set. And even small stones become quite beautiful, when arranged with taste and judgment, in accordance with the conditions I have named, and with the

further condition as to collocation of individual stones in accordance with their size and shape. In pendants, and necklets, and lockets, and brooches there is room for the expression of some definite and intelligible design. The mere alternation of rubies with diamonds in rows or chequer work may, in some instances, achieve all that is needed. But a design of more definite form may often be preferable, especially where the stones at one's disposal are of differing colours and sizes. Then one may construct a suitable bit of leafage or flowerage, duly conventionalised, in accordance with the nature of the available materials, into forms of more or less geometrical severity. It should be noted that moonstones, and white sapphires, in which there often lurks a faint opalescence, accord well with rubies; but it must be kept in mind that the size of the colourless stones which are to be associated with rubies in such designs as those which I have named, is a matter of much moment. It is a mistake to attempt to match the colourless and the coloured stones in respect of size, and generally of shape also. One should be smaller than the other. Large rubies with small moonstones, or small rubies with large moonstones, and similarly, square stones with round, and oblong stones with round, generally produce happier effects than square with square, and oblong with oblong. Pearls accord with rubies, not only by reason of their colour relations, but also on account of their shape. In the case of rubies cut *en cabochon*, brilliant-cut or square step-cut diamonds will be found to yield very satisfactory combinations. A border of small brilliants or roses is a usual and a useful mode of setting off the qualities of a ruby. The colour of a pale stone is heightened by contrast with the colourlessness of the diamonds; the richness of a rich stone is enriched, and a small stone, if surrounded by stones still smaller, becomes magnified in proportion.

Next to the ruby, amongst the red stones, comes the spinel or balais ruby, an entirely different mineral species, without any pleochroism, and inferior in hardness to the true ruby. The scarlet, aurora red, and flame-coloured spinels are the most beautiful; those which verge upon crimson, purple, and violet, looking dull and black at night, but showing very delicate and often rare hues by day. Red spinels accord well with small brilliants, or with larger pearls or moonstones. A fine aurora-red spinel looks well when surrounded with delicate foliage of white, orange, and black enamels. Step-cutting, similar to that employed for emeralds, accords best with the optical qualities of this stone. A biconvex lenticular form may be so adapted to this stone, as to throw a good deal of soft and rich colour into a specimen which would otherwise have had little beauty to recommend it. What richness of hue the finer examples of red spinel may show is to be studied in two specimens in the Townshend collection, South Kensington Museum, Nos. 1,326 and 1,327.

From spinels the passage to garnets is easy. But it is not really difficult to discriminate between the two species, even when the colours seem the same. If you have a ruby, a spinel, and a garnet together, the first will scratch the second and the second the third. The ruby will show two colours in the dichroscope, the spinel and the garnet only

one. The spinel will exhibit no black bars those belonging to the red garnet, when with the spectroscope. And there is a blue due to much absorption of light, in many facets of a garnet, as seen from the "table" stone, which will not be observed in the ruby. The garnet, unless of remarkable size or will hardly be deemed worthy of being in the same costly way as the ruby or spinel, but it may be said that the same gemment suits all these red stones. Yet there are ways in which garnets have, for long and in places, been treated, to which I may refer here. The plates of garnet so large in Anglo-Saxon and Celtic jewels have in the majority of cases, intact to the present. They afford, in their breadths of soft, red, a pleasant contrast to the minute flagellated, and enamel work, with which generally associated. The other employment of the red garnet (and it may be traced back to an earlier date than that I have just cited) is the carbuncle—not necessarily foiled at the back *en cabochon*, slightly hollowed behind, and set in a plain gold surface, the light, as of a coal, quivers in the midst of a good stone. is a lovely disc of antique gold set with carbuncles in the Gold Ornaments Room at the Museum. There is a round carbuncle box with a centre; then four long pointed arms, like elongated pears, radiate from this centre. Naturally with a somewhat similar series of arms, beaten up from the disc of gold, and with nured wires onlaid. There is a work in the piece; the intrinsic value of garnets is quite small, but the effect is de simple, yet rich; solid, yet elegant. Can praise be honestly given to modern garnet? Can we feel a genuine satisfaction either in the design, the execution, or the effect of a big carbuncle of eight lobes, with a six-riveted into the midst of it, the afore being of hard, poor, glittering, much alloy and containing a number of irregular fragments of defective diamonds? The star soon goes and, later on, the diamonds begin to drop. But I will not pursue the history of the farther, and I will refrain from calling attention to other obnoxious modes of using carbuncles say, in a ring with a sham gem on either side.

Amongst orange and yellow stones I unhesitatingly, assign the first place to the zircon—a stone which is sometimes found which may be aptly described as that of parent gold. Next to this comes the chrysoberyl, oressonite; and then we may place the sherry-coloured Brazilian topaz—that it yields, when heated, the finest rose-pink. Yellow sapphires take an almost equal rank with the best topazes, and then the chrysoberyl; and, at some distance, the yellow and the colour combinations have been attempted with these yellow stones; puce-coloured spinel found to associate with the yellow sapphire happily, but there are some enamel answers equally well. Generally, a design of blueish-grey enamel, with minor details in buff and white, develops the richness of the coloured stones.

are two green stones about which some-  
 ought to be said—the emerald and the tour-  
 maline. I do not sympathise with those persons  
 who regard the green of the emerald as vulgar.  
 It is easy to construct a vulgar, coarse orna-  
 ment of emeralds, even if they be of fine  
 quality; so much I will allow. But the emerald,  
 when cut judiciously and quietly mounted,  
 has a rich and refreshing colour, just  
 like the dichroic to show passages of bluish-  
 green. Green tourmalines are much  
 more dichroic, and it is much to be re-  
 lated, with rare exceptions, the patrons of  
 the art still remain ignorant, not only of  
 the rich and varied qualities of the  
 tourmaline, but even of the existence  
 of the emerald. With moonstones, or with grey  
 enamel, long prismatic tourmalines,  
 when cut, afford a delightful colour-combina-  
 tion, especially fitted for larger pieces of personal  
 ornament, such as pendants and brooches. The  
 dark green garnets of the Urals, especially  
 those which are of an olive or pistachio green, are  
 hard and fiery stones, but their softness pre-  
 vents their use in rings. The same objection holds  
 in regard to the lovely stone, the peridot,  
 which species occurs frequently of large size, and  
 is adapted for employment in jewels not  
 subject to much attrition. It is a dichroic stone;  
 well with small puce, violet, or indigo  
 as well with black and white enamel.

However, for lack of time, the varieties of  
 known as aquamarine, the green and blue  
 blue topaz, and the green sapphire, I  
 reserve for a few moments over the sapphire.  
 The opinion of this stone, strong though it is,  
 appears much in the cut specimens we  
 see. But I do not doubt that the twin  
 diversely-coloured light which this stone  
 gives—one azure blue, the other greenish  
 attribute to produce the peculiarly rich  
 and velvety softness. There is a glittering  
 in all the imitations of the sapphire—  
 of their colour, if I may borrow a word  
 from the East, is harsh and unsatisfactory. So a  
 imitation, a kind of lime-spinel made  
 to exhibit apparently the right colour,  
 is at and uninteresting. To my eye, the  
 difference between a true sapphire and a false one  
 is a matter of the difference between a piece of  
 wrought iron, and the same piece in  
 silver.

As to the arrangement of the sapphire  
 ring, so much depends upon its depth of  
 colour and its precise hue, that a general rule  
 is fallacious. Unless it be pale, when  
 seen tourmalines go well with it, the  
 may be most safely associated with pearls,  
 moonstones, or white topazes the  
 old size of the stones being carefully

had time to say something about the  
 both the violet quartz and the harder  
 and rarer violet sapphire. But if I have  
 been compelled to omit such observations, and  
 other things which I would gladly have  
 said, may, perhaps, entertain a reasonable  
 hope that I have found time and opportunity  
 to may stimulate the production, and  
 circulation also, of new and choice colour-  
 ings of precious stones, and may tend to

a more lively and intelligent interest in those  
 little-known and little-prized species, the jargoon,  
 the tourmaline, and the spinel.

Before concluding, I may be permitted to direct  
 your attention to two matters of considerable im-  
 portance in connection with this subject, if our  
 interest is to be sustained, enlarged, and educated.  
 I refer to collections of specimens of precious stones,  
 and to books on the subject. You must go to  
 public museums if you are to see a jargoon or a  
 tourmaline. With a very few exceptions, the  
 largest and most noted London jewellers could not  
 produce a single fine specimen of these curious  
 stones, nor identify them if they were shown to them.  
 I had five good stones mounted by a well-known  
 goldsmith a few years ago, and he misnamed every  
 one of them in the bill. Signor Giuliano, of 116,  
 Piccadilly, is, indeed, the only artist-jeweller whom  
 I know to have made a speciality of the judicious  
 employment of these out-of-way stones.

I commend to your notice three collections of  
 precious stones. In the Museum of Practical  
 Geology, Jermyn-street, there is a small series  
 amongst which the jargoons (especially a green  
 one) are particularly fine. In the Mineral Depart-  
 ment of the British Museum, now at South Ken-  
 sington, a most complete series of every kind of  
 precious stone, distributed, however, in many  
 cases according to their mineralogical position, will  
 be found. And the South Kensington Museum  
 itself owns a fine series of mounted precious stones,  
 178 in number, the bequest of the late Rev.  
 Chauncey Hare Townshend. Unfortunately, the  
 official catalogue (1877) of the Townshend col-  
 lection contains more than twenty incorrect or  
 doubtful attributions. But you will learn much  
 from this series, if you will bear in mind the  
 corrections which I made in this list, in a paper  
 published in the *Spectator*, on July 9th, 1870, which  
 I repeated in the *Quarterly Journal of Science* for  
 January, 1871, and which were adopted by  
 Mr. Hodder M. Westropp, in his compilation,  
 published in 1874, and entitled a "Manual of  
 Precious Stones." I will just give you a single  
 instance of how misleading are the names affixed  
 to some of the Townshend gems. On page 17 of  
 the catalogue (last edition), Nos. 1306 and 1307,  
 and those only, are described as hyacinths,  
 jacinths, or zircons. Both are garnets, and so  
 the Townshend collection would appear to include  
 no representative of this interesting species. But  
 this is not so. For Nos. 1281 and 1282, called  
 garnets, are really zircons; so, probably, is No.  
 1305, which figures as a chrysolite; and there is a  
 fourth characteristic specimen, No. 1322, labelled  
 tourmaline. But if you make these corrections,  
 and 14 others (Nos. 1184, 1188, 1192, 1194, 1195,  
 1277, 1290, 1297, 1298, 1299, 1304, 1309, 1312, and  
 1318), you may study the remainder of these speci-  
 mens with satisfaction and confidence. In a neighbour-  
 ing case to the Townshend series there are some in-  
 teresting specimens lent by the Right Hon. A. J.  
 Beresford Hope. But here note that Nos. 60 and 61  
 are not jacinths, but garnets; that 42 is not a sap-  
 phire, but a bit of blue glass worth 4d. or 6d.; that 53  
 is not an emerald, but a bit of green glass, though  
 next to it is a veritable emerald, or rather two,  
 carved into a vinaigrette; that No. 110, called an  
 aquamarine, is actually a sapphire, and that No.  
 113 is a tourmaline, not an aquamarine.

Of the many books written of late about precious stones, few have any claims to scientific exactness, or afford any satisfactory indication as to the artistic arrangement and use of precious stones. Many interesting facts and fancies about particular stones, and about their commercial aspects, are given in Mr. H. Emanuel's "Diamonds and Precious Stones" (1865); and more particularly in Mr. E. W. Streeter's "Precious Stones and Gems" (1877). But the little volume by M. Louis Dieulaufait, entitled "Diamants et Pierres Précieuses" (1871), which has been translated into English, commends itself on many accounts as the neatest, cheapest, and most trustworthy manual of the subject which has yet appeared. I venture to refer also to my own papers previously named, to one in vol. i. of the *Magazine of Art*, and to a paper in the *Proceedings of the Geologists' Association*, vol. v., No. 7.

In conclusion, I must ask you to pardon the omissions, and they are many, in this paper, in which a large subject had to be handled in a short time. And I must ask you, further, to pardon the imperfect and inadequate manner in which I have attempted to express the results of my own thought and work, in those sections of the subject upon which I have found time to say something. If my paper serves in any way to stimulate and direct thought upon the artistic employment of precious stones, such a result will be as much as I could have hoped for, and more than I have warrant for expecting.

#### DISCUSSION.

The Chairman said they must all be very grateful to Professor Church for the very interesting paper he had given them, and he personally felt specially grateful to him for having exposed the shortcomings of the South Kensington Museum. Nothing was so healthy to any public institution as criticism, and he should not only take advantage of the criticisms he had heard, but should try to get from Professor Church, who seemed to be an authority on a large number of varied subjects, a popular handbook on this subject of precious stones. He had followed the paper with great interest, and he hoped there were some gentlemen present who would be prepared to discuss it.

Mr. Edmunds said he must confess that his business as a jeweller was carried on more by rule of thumb than on scientific principles; he was guided principally by what would sell, and therefore he could not pretend to instruct the meeting in any way. He cordially agreed with what the Chairman had said as to the value of the paper, and should be very much pleased to see a taste for precious stones cultivated. At present the jewellery business was guided mainly by intrinsic value, and there was not nearly so much taste and skill exercised in mounting as might be seen on the Continent. There was room for a great deal of improvement in this direction, and he hoped that this paper might have some good effect in directing more attention to this subject.

Mr. Higgins, after complimenting Professor Church on the paper, said his opinion was that when they had anything so magnificent as a diamond, ruby, or emerald, it was the duty of the manufacturer to assist, by a nice combination of colour and art in the setting to improve the appearance of those splendid gems. They were also indebted to Professor Church for information as to how to distinguish real from spurious gems. He did not know that he was ever more pleased than on one occasion last year, when he heard a paper at the Royal Society

on the manufacture of diamonds. His satisfaction was not at the fact that diamonds had been made, because he thought that would be a most unscientific application of science, but it was an extremely beautiful fact that the ingenuity of the craftsman produced what he believed was generally accepted to be the purest thing in nature, the pure colourless diamond. At the same time, he believed in the very little prospect of the manufacture being carried out, except as a scientific experiment; that, in fact, no chance of getting manufacture to supplant the work of Nature. In his opinion, jeweller's art had very much advanced in the last few years, especially since the Exhibition of 1851. There had been a vast improvement in the setting of gems, and further advances might be expected from that paper, and a study of the results of which reference had been made.

Mr. James Price said he was sure Professor Church would pardon him if he ventured mildly to criticise one or two points in the paper. He quite agreed that a great deal depended on the harmony with which the colours were blended, in the production of work in precious stones, and also in the form given to them; but with regard to the condemnation which had been passed on the practice of cutting stones as they were, there was this to be said, in the case of rubies, and other stones, if they were sufficiently pure to show that brilliancy for which they were so much valued, and in which their principal value consisted, it would be an immense sacrifice to cut them in this way when they were not of first-rate quality, it was an advantage to cut them *en cabochon*, because it was to a great extent the flaws and faults which the stone retained. That was the principal reason for this form; and another reason was that they were in great demand than faceted stones of the same class. Of course, the sale of stones, and the work made out of them, would always influence the dealer in them, and there was a much greater demand for *cabochon* stones, especially in oriental climates, probably the brightness of the light led them to look more to colour than brilliancy in stones. In the belts of swords and other articles where they were used, a stone *en cabochon* gave a better effect than a faceted one; and, in this country, a gentleman who wished to wear a ring or a pin might not unnaturally prefer the appearance of a *cabochon* than one which would be more glaring, and as some might say, vulgar. Again, rubies made a beautiful combination with diamonds, as Professor Church had himself pointed out in such a position they would require colour as well as brilliancy. Then Professor Church had argued against the use made of irregular monster pearls, forming them into the representation of some object; but as they were formed by nature in these irregular shapes, in which they were altogether inapplicable for necklaces or similar poses, the jeweller could only use them by fashioning them into the shape of a beetle, or any other form which might suggest itself as most suitable to the particular pearl. He had condemned some of the common forms of jewels in this country, particularly the half-hoop ruby ring, which it only showed the rubies. But such a ring was intended to be worn as a single article of jewellery, it would be accompanied by a diamond ring, or some other of the kind, so that one would set off the other, and regard to the moonstone being very suitable for a ring, he would point out that it had no intrinsic value, scarcely more than a pebble or an agate, and, if it were cut, it would be useless and inconsistent for a jeweller to do it, because he would find no purchasers for these stones, which might look very well, but which were means of disposing of them. They might be made into beautiful work of art for a museum, but for

would be useless. The same with regard to anybody asked for them, and no shop kept by did, they would not sell them, and therefore were not mounted. The aristocracy, paid great attention to precious stones, as to value, and distinguishing peculiarities, saw very well that it was not difficult to have these stones from rubies, because they were much softer. With regard to the emerald valued by some people, and considered as just now—only temporarily, he believed so. In all ages it had been highly valued, but he believed it would always be of great value. It had a certain soft beauty always been admired, and it formed a combination with the diamond. In these it depended on fashion, and, in the present, the sapphire was greatly in demand, and therefore mounted and sold; and he believed the day would come round again, and possibly the tourmaline might, at some future time, and also. At present, though they might be as beautiful as works of art, they would be fit for museum purposes. What was wanted was a higher standard of talent should be employed, in the selection of those articles in which precious stones were used for artistic and ornamental purposes. Looking back hundreds of years, to the time of Benvenuto Cellini, he would find a much higher standard than existing, with all our advances in steam, machinery, and the like, were much behind in such matters. Great progress had been made in architecture, sculpture, and painting, and he hoped the reading of this paper might do the same to this subject also, and that they might encourage those who possessed higher training to devote themselves, as they did in former times, to the working up of these highly prized and productions of nature. In the arts he had seen that practical men were highly cultivated, and they did not say it was not so; the practical men were the artists, and the designers were only one step removed. He wanted a higher order of intellect devoted to the subject, as they might hope to rival the works of which at present they were far from doing. He had listened with great pleasure to the lecture, and at the same time he thought Professor Church had put the cart before the horse. The subject was a very difficult subject, and was very important, but until it was so, and the public could not see a distinction between precious stones, it was of little use for the jeweller to supply them in any artistic form; hence he simply made what he believed the Chairman would bear him. In the Science and Art Examinations, only a small amount went up for mineralogy, as compared with the other subjects, and until it was improved, he feared no advance would be in the artistic production of jewellery. Prior to the time when France in all art matters, was only taught to a few who were supposed to do it; now it was taught to almost everybody, and we were becoming an artistic nation, not only designers for our own use, but for others, especially the United States. When mineralogy was also given, we might hope to make similar advances. When at the Paris Exhibition, he was struck by the dexterity of the French in the setting of jewellery, but he hoped through the efforts of the Society, and the City Guilds Institute, some improvement might be made. At the present time, the public was simply to money value, and would not care from which they did not expect to reap a profit, and it would only be by holding out to the public that artistic work would command a high price, and that attention would be paid to the subject, and that improvement might be expected.

Mr. Neckold, as a practical lapidary, did not agree with Mr. Price that the cutting of stones *en cabochon* concealed their faults; on the contrary, he thought it would show them up. Again, with regard to moonstones not being more valuable than pebbles, he could say from experience that they were much in demand at the present time, and that plenty of buyers could be found. Emeralds were still very valuable, and would fetch a long price.

Mr. Price said his contention was that the purest stones, as a rule, were not *en cabochon*, and he believed everyone of experience would confirm his opinion. Moonstones were not of any intrinsic value, as compared to precious stones. He was aware that there was a considerable demand for them at present for the American market, where they were used for pebble work.

Mr. William Botly said there were some of the finest precious stones ever collected together at the Paris Exhibition. He remembered in particular two enormous emeralds in a pair of bracelets, several hundred pounds in value, which he had the pleasure of examining. He noticed there was a difference in the colour of them, and though the proprietor would not at first admit that they were not a perfect match, he at last acknowledged that there was a difference, and that one was worth £50 more than the other. They were much indebted to Professor Church for bringing this subject forward, and insisting as he had on the importance of due care and skill in the arrangement of form and colour, for it was only by attention to these points that we could ever hope to rival the French and other workmen. Although Amsterdam had for many years stood almost alone in the cutting of diamonds, he understood that an immense deal was now being done in England. It had been said that the Koh-i-noor had been immensely reduced in size from injudicious cutting. He believed that both the late Prince Consort and the Duke of Wellington were consulted, and were present at the cutting; but if the facts were as represented, it showed the great importance of more perfect knowledge in the manipulation of precious stones.

Mr. C. J. Parton, while quite agreeing with Professor Church that there was little talent displayed in the mounting of precious stones, thought they could hardly wonder at the fact. In olden times jewellery was only worn by a few, and the man who mounted the stones came into direct contact with those who wore them, and he was well paid for his labour. It would be scarcely thought fit to apprentice a boy to an artist, who did not show some artistic talent, but jewellery was taken up as a trade, not as an art, and boys were apprenticed to it as to any mechanical trade without any talent at all. It was simply because there was not sufficient demand for artistic work, that they did not have it. He was quite sure that when the public taste was shown sufficiently to induce men of talent to devote themselves to it, knowing that they would receive that amount of remuneration due to art work, there would be a great improvement. But when a workman simply received an order for one article, and found a gross sold better, he would naturally devote himself to the gross.

Mr. Ford desired to corroborate the remarks which had been made by Mr. Price. He said that *cabochons*, as generally cut, hid the flaws in various stones, and as a lapidary of some forty years' experience, he (Mr. Ford), could confirm that statement, and he knew that in many cases, although not in all, it was adopted for that purpose. Moonstones were very common, and he had sold them in quantities at 4d. and 6d. each. It was not to be supposed that jewellery of fine quality would be associated with stones of that small value. As to the emerald, he would say that

It was the most beautiful stone of any next to the ruby, and he could not imagine how any one could call it vulgar. With regard to diamond cutting, the practice had now so improved and greatly increased in amount, that he believed in a few years' time the trade would be developed in London to the extent that there would be factories, as there were in Amsterdam, having two or three hundred men at work.

Professor Church, in reply, referred to the exact words he had used with reference to cutting stones as decoration; he did not give it as his own opinion, or as the practice, but what had been advanced in several books, and especially in a lecture given by Mr. Ruskin some years ago at Oxford, in which he objected to any faceted stones at all. And there were several others of the same school who had objected over and over again to any faceted stones, good, bad, or indifferent. He did not agree that the commercial value of a material which was fairly hard, and useful for artistic purposes, was the sole criterion as to its employment. If red, blue, or other enamels were used, whose intrinsic value was a very small sum per pound, and most superb ornaments were produced with it in combination with gold and precious stones, why should you not use a lovely, brilliant, hard substance like the moonstone in decorative jewel work. There were one or two specimens in the case on the table which were worthy examples of the exercise of a good deal of labour. It was quite true that the spinel was not quite as hard as the ruby, but it was not very far short of it, as would be seen by the table. His own opinion of the emerald was that it was a lovely stone, and with regard to the jargon and tourmaline, what they wanted was to lead public opinion to appreciate them. Of course they would not pay a very few people would buy them, but there were some collectors who did buy these stones, and he knew of many pieces of spinel work and jargon work which had passed into very good hands. It was really not necessary to know much about mineralogy to be able to distinguish these things. An educated, keen sight, and a few simple instruments, used in a moment, would enable anyone to distinguish any of the stones which otherwise were rather difficult to determine without them. Lastly, he would say that the main object of his paper had been to introduce a discussion on the subject, and to show what might be done in various little worked directions.

The Chairman, in proposing a vote of thanks to Professor Church for his paper, said he hoped that a great deal of good would result from it, and that attention would be drawn to the various collections which had been mentioned. He had lived for 25 years at the South Kensington Museum, but he should take an early opportunity of inspecting the Townshend collection with a renewed interest, and he trusted that, out of the million of visitors who honoured the Museum during the year, many would be led to study that collection with more attention. The authorities, after what had been said, would take care to have all the specimens properly labelled, and possibly they might be able to add to the collection some of the specimens of which Professor Church had referred.

The vote of thanks was passed unanimously, and the meeting separated.

## MISCELLANEOUS.

### BREAD REFORM.

Dr. Graham, the author of the *Cantor Lectures on "The Chemistry of Bread-making,"* delivered in 1879, has published in the *Mirror* of the 7th February, a long letter on the subject of what is called "Bread Reform."

Dr. Graham combats many of the statements put forward at the Mansion-house last December, in favour

of bread including the bran and husk.

by summing up the doctrines put forth by the Reform League as follows:—"1st. That we not contain sufficient albuminoids for life and that wheat-meal bread does contain a least, is incomparably better adapted for life than white bread. 2nd. They assert—or, at least, that the albuminoids of bran are of the value to man as the higher albuminoids of wheat. 3rd. They assert that the greater part of it is removed with the removal of the husk to support their views as to the relative value of meal and fine flour by economic considerations. 4th. They conclude that the cheaper is by far the better repudiate the universal conclusions arrived at since the relative merits of white and brown bread being not due to the dictates of nature but to the selection of that which is best for man, by an ignorant and debased taste. 5th. They ignore the impossibility of obtaining a well-aerated bread by the fermentation process. 6th. Recognising this, they imply the non-adoption of the Daughlish or other artificial processes."

Dr. Graham then proceeds to examine the arguments put forward by various members of the Conference. He commences with Mr. Secretary of the League, who maintains that nourishing bread is sufficient to support population. To this Dr. Graham objects alone is an insufficient diet for a man and an animal. The next point taken up is the nutritive value of white flour, which is also said to contain less nourishment. To this Dr. Graham objects that the amount of bread eaten by the people of Vienna, Dresden, or Moscow, all rich in wheat, but deficient in bran, could be injurious to them, and difficult to digest. He reasons that Frenchmen can easily digest large loaves of bread, is simply because the bran has been removed. Some enthusiastic remarks of Miss Y. on the probability of pauperism, disease, and other evils, are also alluded to by the use of whole-meal bread by Dr. Graham.

The next speaker was Professor Henslow, who said that "the grain consisted of two parts, white tissue, which contained a preponderance of but little nutritive value, and the outer gluten phosphates, &c."

To this Dr. Graham replies:—"It is a miller or baker to learn that the fine flour of France, Hungary, and other countries is deficient in nutritive value, because deficient in gluten, being that these flours are richer than the amount of gluten they contain. Professor Henslow went only to assert that, in the ratio of albuminoids (not gluten), but it was high as compared with starch, as he has reported in your paper, the statement implies that the greater portion of the nutritive value of the grain, being deficient in gluten and rich in starch, is of little nutritive value. It is almost certain that the statement is erroneous."

Professor Church is the next antagonist. He states that the finest flour contains a percentage of nitrogenous substances is 1.5 per cent. Dr. Graham. By Professor Church's statement Graham is led to comment on the following terms—"Here and there a stimulant, it may be, by the absurd and filthy concomitants of the fermentation process since removed by the introduction of appliances—will eat and try to live as well as thirty years' experience has shown, large will have none of it. Indeed, most

in their trial, have at last gone back to the "favoured product of fermentation." The sum of bread-making in Europe, as compared with the fermentation process, is utterly insignificant. In short, on this matter, as on the 6 man and other articles of diet, hasty shying mere chemical data as a guide, have to date to the world as to what it should eat it should drink. The world eats and it is like, not what orals and groundless, and in so doing it is, in the long run, and there an instinctive craving may be eye, but, as a rule, where natural preferences of science conflict, the latter has gone wrong and ill-founded assumptions.

Church gave the ratio of albuminoids to 1 in whole meal bread, but only 1 to 7½ white bread. This assertion is disputed by Latham, who says—"Even with English the albuminoids to starch is much higher and as two-thirds of all the wheat we consumed from countries of more favourable climates, and, therefore, with a higher of the albuminoids, the statement in regard is utterly erroneous."

On this goes on:—"The relative dietetic albuminoids of the bran and the gluten of say now be discussed by me, in the examination proposition, which, briefly put, is rates of bran for human food, basing there on chemical analysis, assert that the of bran, and also, as necessarily arising and adhesion to mere chemical data, those are, peas, linseed cake, and deoctorated finely ground, are of high dietetic value voracious animal, such as man. How comes argue, while denouncing in no measured removal of bran from our bread material, ally and consistently, from their analytical aged us to go back to the use of peas and once so common, and even yet not absent. Again, considering the high per- albuminoids in barley, oats, in beans, peas, y have they not had the courage of their and urged that all these should be ground used as human food, and not given, as at r cattle, to elaborate into higher products ation of our carnivorous instincts? Liebig y was a great chemist, but he was also before liable to err; and considering the knowledge at the time, and the speculative in Giosseru philosopher, it is not strange ad at many erroneous conclusions on the instation. Bearing in mind the cheapness, peas, and feeding barley compared with insufficient is the logic of the following:—

rietti informed the meeting that Liebig that we made a very bad use of our corn, e flour ourselves and giving the coarsest cattle. We also made bad use of our e paid at the rate of from 10d. to 14d. for hold only cost us 2d., and we fed our resting us 2d., whereas we only ought to hing per pound for it. If we eat the te of our grain in the shape of pork in- r, Liebig thought, with a good deal of e were very bad economists, and not very ear, hear, and laughter.) It also followed had food to our cattle, whilst we did not food for ourselves."

crude argument is to be allowed ignor- e obscure questions of physiology, why did he urge on us to eat the materials own, all cheaper and far richer in album- and, instead of giving them to our cattle? he views held at the so-called conference,

based as they are on mere chemical data, and utterly oblivious of the vast difference between the digestive machinery and power of an herbivorous animal, with its complex digestive apparatus, and that of the simple one-stomached semi-carnivorous man, have been over and over again repudiated by the instinctive cravings of mankind.

The speakers at the Bread Reform Conference made use of chemical analysis to show that the world is utterly wrong in preferring white bread to brown bread, or whole-meal bread. Instinctive selection and preference is ignorant and wasteful, and chemical analysis is said to prove it, and therefore we must eat bran, or be guilty of sinful waste and crime ignorance of what they are pleased to call science. But why listen to likes and dislikes at all, and not urge upon all the necessity of eating gram, hay, oats, straw, and any other vegetable substance that chemical analysis indicates to be valuable, and that good economy shows to be cheap. This may seem absurd, but it is to what the chemical theories of the bread reformers must drive them, if their common sense be not better than their science. Now, the instinctive common sense of the world has relegated bran, along with gram, beans, and peas to our cattle, and in spite of an energetic and well-meant, though unscientific movement, the world will continue in this course, because based on real physiological necessities of animal digestion and elaboration, and not on hasty scientific, so-called, assumptions. Though a chemist myself, I must protest against obscure physiological phenomena, requiring all the highest powers of the ablest physiologist to be able to do more than guess at darkly, being authoritatively settled by the mere chemical analyst.

The ablest physiologists of Europe are unable to explain the obscure phenomena of digestion, elaboration, and repair of the tissues, but none of them would hesitate to reject with contempt statements as to the dietetic value of food substances based on mere chemical analysis. In short, chemical analysis is utterly worthless in settling this question; we require other and more legitimate scientific aid, but even physiology is as yet unable to authoritatively dictate to us in this matter, and when it is in such a position there can be but little doubt that its conclusions will, in the main, coincide with those adopted by the instinctive preferences of man; and these are against bran, beans, and peas, and such like cheap and nitrogenous products."

Professor Graham then discusses the statement that the greater part of the phosphates is removed in the bran. On this point he quotes Messrs. Washly and Cooper, in opposition to Professors Church and Henslow. Dr. Graham then remarks:—"The children of the poor, insufficiently supplied with milk, may be deprived of a sufficiency of bone-forming materials when dieted too largely on bread. This, however, can easily and cheaply be overcome by the addition of precipitated bone phosphate along with malt in the fermentation process, or still more simply by the use of the process already patented for the treatment of yeast for bread-making. This treatment adds bone-forming material to stimulate the yeast organism, and also to increase the quantity of bone-forming matter in our bread. As this process has for its object to replace dear German yeast by cheap and powerful English yeast, this aspect of the question can be readily and economically met."

The fourth proposition is that whole-meal is cheaper than fine flour, and, therefore, economically to be preferred. On this head Dr. Graham remarks that the poor in large towns do not get the finest white bread, but rather bread in which some finely-ground bran exists, and, therefore, he argues that ill-fed, rickety children must be affected by other causes than the use of white bread."

Dr. Graham then passes on to the sixth proposition given in his list. On this he says:—"I have, in my lectures at the Society of Arts, explained why the ground bran and ground embryo act so injuriously in the fermentation process of bread-making, and have

there shown that these albuminoids, like those in barley meal, have an energetic diastatic action on the starch, producing too much maltose and dextrin, which have an injurious effect on the colour of the baked bread. Again, these albuminoids, together with those found in barley, beans, and peas, have not the resisting elastic action of the gluten of wheat, and, therefore, are unable to produce the light, well-aerated, and easily-digested wheaten bread, such as we find in a good white loaf made by the fermentation process. This matter need not again be discussed in our columns, because your readers have already had the opportunity of studying these lectures in your issues of February, 1880, and subsequent months. It will suffice that I again repeat what is, after all, known to every baker, that finely-ground bran injures the bread by its injurious action in the fermentation process; and, further, that ill-elaborated wheats of our own country, of bad harvest conditions, though richer in albuminoids than that of excellent harvests, are comparatively poor in gluten, the invaluable essential for bread-making and for food. Here I would again state that of all cereals wheat alone can satisfy the conditions of the fermentation process of bread-making, and even with wheat, the inferior—and, from a dietetic point of view, comparatively useless—bran must be removed."

In conclusion, he sums up the statements made by the advocates for the consumption of bran, by saying that, "they fail to support their assertions on the following points:—1st. That white bread is deficient in flesh-formers, but that it is not so if mixed with some finely-ground bran. 2nd. In their contention, explicit or implied, by their strange adherence to chemical analysis, that all albuminoids, no matter the origin, are of equal value to the gluten of wheat and the albuminoids of flesh for semi-carnivorous man. 3rd. In their contention that three-fourths of the bone material of the ash of wheat is removed by the removal of the bran. Further, in using economical and analytical data to support them in their charge of ignorance on the part of the miller, baker, and consumer of bread, they have omitted to urge the far greater superiority, in both of these respects, of beans, peas, barley, linseed-cake, &c., which, from their analytical standpoint, they were bound logically to do. And then remarks that, "the farmer, miller, and baker must strive to improve the dietetic value of our bread in the following respects:—(a.) By the early kiln-drying of ill-matured and ill-harvested wheats of our own country. (b.) By the judicious admixture of 'hard'—that is, highly elaborated and matured—foreign wheats. (c.) By the improvement of our yeast. (d.) And lastly, by taking care that the flour of our 'soft,' and too often ill-matured home wheats, be not used in the preparation of the 'ferment' and 'sponge,' but only in the 'dough' stage. Such, it seems to me, are the right methods to adopt in the improvement of the bread of the poor, and not by the admixture of bran, however finely ground. The bran of wheat—like the skin of the potato, turnip, and other vegetable products, is best given to our cattle for elaboration into higher albuminoids for our use, notwithstanding the analytical arguments of the Bread Reform League."

### MARBLE QUARRIES OF ALGERIA.

Thirty-four kilomètres north-east of Oran, on the high road to Arzeu and Mostaganem, is the small village of Mefessour; a branch road to the north-west leads to the still smaller village of Kleber. Above this rises the imposing mountain called Djebel Orouse, generally called "Montagne Grise" from its arid, grey appearance. The chain of hills, the highest point of which is about 2,000 feet above the sea, stretches in a north-easterly direction from Cape Aiguille to Cape Carbon, and includes Cape Ferrat. The central part of

the range forms an elevated plateau, a level, with a superficies of 1,500 or 2,000 hardly any soil or vegetation, nothing, it is as Consul Playfair states in his last report, an uninterrupted mass of marble and breccia, and finest, probably, that the world contains. Playfair gives it as his opinion that, the Mosque of Cordova, which, as regards its architecture, is an epitome of all the finest Roman and is marble of greater beauty or variety to as far as quantity is concerned, there is all France and Italy together, not excepting the Carrara. The discovery is due to Monte, who was also fortunate enough to discover well-known quarries of alabaster, called "onix," at Ain Tekbulet, near Tlemcen. He obtained them from the Arabs for a mere trifle, and the country was still unsubdued, and he approached them without danger to his life. He obtained a concession of the "Montagne Grise" for a period of years, and on very favourable terms. The area is about 1,500 or 2,000 acres only, but he obtained all the land round about in which chance of marble being found, amounting to 14,400 acres, so as to avoid the possibility of competition. The whole of this area is an unbroken mass of marble and breccia, which only requires to be detached and carried away; roads have been made in every direction, so that there is no practical difficulty in doing either. All over the surface of the plateau may be seen circular depressions, the sites of Roman quarries, and these, to indicate the position of the different quarries, the soil, where any exists, is of a deep red colour, containing small particles of iron ore; mine water, containing mineral exist in some places, and have been used, but there is not a sufficient quantity of water to make this remunerative. The ore has been used for its purpose—a much more important one than the mining of an infinite variety of rich tints to the breccia rocks. Consul Playfair remarks that he would say all I wish on this subject, but he is charged with exaggeration, but in substance he says the two days I spent in examining the ground in the direction I passed from one marvel to another, in amazement at the magnificence of the marble has so long lain, I will not say concealed, but hidden to the most superficial gaze there." He found not in isolated spots, or in limited quantities, but in boundless profusion, and capable of being worked in liths of any size. Although many varieties in practically inexhaustible quantities, the common is the "Giallo Antico." Other varieties of tint are found, and Signor Caviglioglio states that some of it is precisely similar to the columns of the Pantheon at Rome are made of a delicate and beautiful, as well as the most valuable marble of an exquisite rose tint, which is used either in large masses or in the finest sculpture. Consul Playfair states that he has seen made of it, which could hardly be distinguished from pink coral, and blocks from which the finest might be cut. With this rose-tinted marble he found a rich creamy white, and another white; but it is in the breccias that the most beautiful of form and colour is to be found, they are perfectly homogeneous, the pebbles of which form the mass being of equal size, taking an equally good polish; there is no advantage, they leave no holes requiring to be filled with artificial cement when worked. In 1878, there was a magnificent marble work in the centre of the Galerie des Beaux-Arts by Monsieur Cantini, of Marseilles, which he obtained the gold medal. Almost every year with this trophy, Consul Playfair says he has obtained from the quarries of Kleber. From in

pear that the cost of extracting the marble and putting it to the sea for shipment is not great. The extraction of the blocks costs 50 francs per cubic metre to transport to Oran (about 27 miles) costs 10 francs, and to Arzew (12 miles) 25 francs. Royalties in addition to about 30 francs per cubic metre. It is stated that the marble could be laid on the sea for 120 francs per cubic metre, or landed on shore for less than 200 francs. The only other marble found in Algeria are the Algerian marbles mentioned, the breccia of Chenonah, of a fine quality, and the white marble of Filfila, which places, which can never compete with

#### CULTIVATION OF THE CHESTNUT IN TUSCANY.

Chestnut tree has existed for centuries in Tuscany, and at one time nearly every hill and mountain side was covered with its foliage. The number of trees in Tuscany and Lucca at the present time is estimated at several millions, and the nut and wood are valued more to the maintenance of the population of the districts than any other productive places, in fact, wheat, flour and corn meal are superseded by the chestnut flour, which is sold at a higher and much cheaper as an article of food than wheat. The trees grow to the height of 60 or 70 feet, and reach maturity at the age of 60 years; its productiveness lasts for more than 100 years. In some parts of Tuscany it is largely cultivated, and is raised from the seed or nut; the larger Spanish chestnut is cultivated from grafting on other trees. Mr. Schuyler Crosby, the United States Consul at Florence, states that there are six kinds of chestnuts cultivated—the Marone, the Castagno, or Carrara, the Pastineo, the Rosolo, the Castagno, and the Brandigliano. The method of cultivation is as follows:—The chestnut is raised from seed, and is planted in earth which has been softened and is carefully worked over. The plantations are situated near a stream, and the ground shaded by other trees placed close together. The space between the cultivation of the chestnut is divided into six or seven feet wide, and in each of these a hole is dug about three inches deep, and at a distance of about six inches from each other. In these holes the seeds are placed, with the germs downwards. The chestnut is matured not largely resorted to, although the object of rendering the plants more vigorous as it is dangerous, on account of transplanting the young tree, finding itself on soil less than it has been accustomed to, easily languishes. After two years the plants are transplanted to the site of the plantation, where they remain for three years, after which they are placed where they are to remain permanently. The season usually for transplanting is after the falling of the leaves, and it is frequently done even as late as March. There are two methods of grafting—(which is done at the age of five or six years)—the primitive method of inserting the bud of a branch, with a slit in it, where it is required, or other substances. The other, which has proved the most successful in its use in cutting large rings of bark from the trunk of the large or Spanish chestnut, and placing rings of the ordinary kind; this is a very tedious, requiring great care, and is performed in the following manner:—The bark of the chestnut is cut into circles on the twigs, where it is to appear, care being taken to have one or two rings of bark left on each circle or cylinder, the bark is then cut out to loosen it from its position, and is removed by hand, until a hollow cylinder of bark is left, which is then drawn up by the stem, that

has been previously denuded of its bark in like manner. The cylinder of bark is then carried to the stem of the tree, which is grafted. This stem, having been previously denuded of its bark, and cut off down to the place where the ring is to be put on, is then covered with the ring, which unites with the growing bark, and sends out shoots of its own variety. In this manner a tree is covered with these rings, and the natural branches being cut down, all the force of the tree is expended in throwing out the shoots of the large chestnut from the grafted branches. Great care is always taken to cut off all shoots of the common chestnut that may appear near the grafted part, as they interfere with the full development of the part grafted. The operation of grafting by rings is practised in Tuscany from the 10th of April to the 1st of May, that being the time when the sap is running most freely, just before the leaves and buds come out. A method of preserving the grafting buds so that they may be good even after a year, is to place them in tin tubes filled with honey, and hermetically sealed immediately on their removal from the tree; another method of transporting the grafting buds, is by putting them into hermetically sealed tubes filled with water; this method can only be used for transporting the buds for distances accomplished under forty days. The chestnut produces flowers which after the usual process of the male pollen being deposited on the ovaries of the female flower, become chestnuts or the seeds of the tree; this change of the flower into the nut takes place about the end of July, and it is easy to foretell the crop of the year by the state of the nut germs, for although the flowers may have been abundant, fecundation may not have taken place largely, and it is only by watching the tree carefully after it has flowered, that a judgment can be formed as to whether the production will be good. The ovaries that are not fecundated by the flowers change into useless shells, but those which are fecundated become enclosed in buds containing one, two, or even three chestnuts. The nuts arrive at maturity in two months after flowering, that is to say, in October, and then fall to the ground; they are also beaten from the trees by peasants armed with long poles, but this is only occasionally done, as it seriously injures future fruit buds, and affects the yield of the tree for another year. The chestnut is pruned and trimmed every three years, which, while helping the tree to bear more abundantly, produces wood for fuel and other purposes, and the smaller twigs and branches, which are dried and used later for drying the nuts. The leaves are also gathered when green and young, and pressed flat in large bundles, and are then used for putting under pat of butter, and in making a kind of cake called "necci."

The Spanish chestnut has been cultivated with more than usual care and success in the province of Lucca, owing to the laws to protect it from destruction, passed by the Luccan Republic in the eleventh century. The chestnut is a very healthy tree; in fact, the only disease to which it is liable is internal decay of the trunk. Cases have been known where the whole life of the tree has been carried on through the external bark, while the interior was completely destroyed; the only way to arrest this disease is by burning out the whole of the interior of the tree by a slow fire. After the nuts are gathered, which is done by picking up those which have fallen, and not by beating the tree, they are deposited in huts, in the upper part of which deep trays are constructed on which the nuts are placed to the depth of six inches; in these huts slow fires of green wood are kept up, until they become hard and dry. They are then carried to the mill, where they are ground into flour, in the same manner as corn or wheat. From this flour many preparations are made, such as "polenta," and various kinds of cakes, fritters, and even a heavy kind of bread. The different ways of cooking the chestnut flour are known under the popular names of "necci," "pattoni," "castagnacci."

"caldi," "fritelli," &c., and the food so made is sweet and agreeable to the taste. The country people cook the chestnuts in water, and make use of this water as a medicine for chest diseases, colds, and coughs, and in most cases it has proved beneficial. The food made of the chestnut, which is most in favour, is the "polenta," made by simply boiling the chestnut flour in water for ten or fifteen minutes, with a little salt to flavour it, care being taken to keep up a constant movement of the paste, so that no part becomes burnt, which would thus spoil the mess; it is eaten with cream, butter, ham, &c., and is most healthy and nutritious. Another kind of food made from the chestnut is called "necci," which is flour formed into a cake, and is made by first mixing the flour with cold water, and making cakes piled on each other, and separated by chestnut leaves, pressed for the purpose, and moistened by water; the whole mass is then cooked over a hot fire, and the cakes taken off one by one, when the leaves are almost burnt. These cakes are generally eaten with cheese, Bologna sausage, and meat. Consul Crosby states that, in those regions where the inhabitants live almost entirely on the chestnut, they are of better appearance, and as strong as those who live on what is considered more wholesome and nutritious food.

### GOLD MINING IN QUEENSLAND.

It appears from a report, issued by the Department of Mines, Queensland, which has just been presented to Parliament, that the approximate yield of gold in the year 1879, amounted to 288,556 ounces, as compared with 309,612 ounces in 1878. This decrease of 21,056 ounces represents a loss of £73,696, and would seem on a superficial examination to be a very severe falling off in the gold yield of the colony. But a decrease was anticipated, owing to the bed of the Palmer River (the principal deposit of alluvial gold) and its auriferous tributaries having been to a great extent repeatedly worked over, and consequently until new auriferous ground is discovered, a falling off must be expected. Although there is this considerable decrease in the quantity of alluvial gold produced, it has not been from the individual earnings of the alluvial miners being less than in the previous year, but from the decrease in the number of that class of miners. There has, in fact, been more gold produced in the Palmer district, relatively to the number of miners working during 1879, than there was during the previous year. This is accounted for by the improved system upon which the Chinese now work, that is, in large gangs sluicing, instead of as formerly, in small parties cradling, and by the discovery of several new patches of ground which, although of small extent, and soon worked out, yet yielded large returns.

The quantity of gold exported in 1879 amounted to 281,552 ounces, and it will be seen that there is a difference of 7,004 ounces between the amount exported, and that actually produced. This is due to the fact that a considerable quantity of gold is carried away in small parcels, by persons who do not make entries of it at the Customs. The number of miners at work in the colony in 1879 shows a decrease, as in 1878 there were 2,980 European quartz miners, 654 European alluvial miners, and 1,095 Chinese alluvial miners, in all 14,490; whereas in 1879, there were 2,750 European quartz miners, 441 European alluvial miners, and 5,621 Chinese alluvial miners, in all 8,812. Mr. Lukin, the under-secretary of mines, explains that this is but a rough statement, as the wardens of the separate gold-producing districts have not the means of obtaining a very accurate estimate; it is possible to arrive at a reasonably correct calculation of the number of settled quartz miners on the older fields, but not of the large floating population of alluvial miners, Chinese, and prospectors, scattered over thousands of square miles of

country. The decrease in the number of Chinese is very great; it appears, however, that 889 district alone, that of Cookstown, for China, 54 have arrived from that country. Numbers for southern ports, many have taken to agricultural pursuits, a considerable number have themselves over the many old alluvial fields colony, and moving about in parties have escaped enumeration in the totals returned by the wardens as engaged in mining. Death of a considerable number in the decrease; the among the Chinese having been abundant during the early part of 1879. The fall in the number of European alluvial miners is for by the exhaustion of the alluvial fields decrease in the number of quartz miners has principally on the far northern fields, where they have been disheartened by the difficulties against which they have had to contend, chiefly through the want of capital necessary to work the ground. The commercial depression, so general through the colonies, has debarred the storekeepers, traders and speculators from backing the working of the previous years, when money was plentiful and easily obtained. Quartz mining is, however, in a factory condition, as in the principal reefs of those of Charters Towers, Gympie, Hodgkinson, wood, Palmer, and Etheridge and Gilbert—the gold, in 1879, amounted to 175,668 ounces amount, though slightly less than that produced two previous years, considerably exceeds that when it amounted to 151,687 ounces. This however, is nothing more than the ordinary fall observable in the returns from all established during a series of years. Mr. Bligh, the warden of the district of Gympie, partly accounts for it by that, in some dividend-paying claims, raising has been suspended for a time during the erection of mining machinery, a change which, though immediately falling off in the production, inevitably to a better yield in the future. There is no in the richness of stone at the deeper levels worked, and new and promising ground has been discovered. Several new reefs, distant about ten miles from Gympie, but within the Gympie Gold Field have been tried. A trial crushing from the first covered (the Veteran) gave a yield of nearly 1 ton to the ton. Equally satisfactory reports come from other districts. A comparison of the amount won with the number of miners working, and the position of the individual miner can be proved. The actual number of men working Europeans, 3,191; Chinese, 5,621; making 8,812. As the total yield of gold for the 288,556 ounces, which, at an average of 1 ounce, represented £1,009,946, it places the average each individual miner at £114 12s. For the year it was £74 15s. 8d. Excluding alluvial mining is mainly carried on by Chinese, and taking reefing, which is exclusively in the hands of Europeans, it appears that the yield in 1879 was 189,7 total value, £664,094; average earnings of £250; against 179,038 ounces in 1878, value average earning of each miner, £201 9s. 9d.

### CORRESPONDENCE.

#### SIGNALLING BY SOUND.

Attention having been called to the subject of signals in your *Journal*, it may not be uninteresting to your readers to know that we have recently and patented a sound signal whistle, that will

vate in contrast, and also in combination. This apparatus has been submitted by us to R. Collinson, Deputy Master of the Trinity, Thomas Gray, Marine Secretary to the Admiralty, and Mr. Douglass, Chief Engineer to Home, and experiments were made by us with those gentlemen at Blackwall, on the 18th. We venture to say that this sound signal, will prove a great boon to our preventing collision, and also for coast work. We shall be glad to give further information on application to  
SMITH, BROTHERS, AND CO.,  
Broom Works, near Nottingham.

ing is the description of the instrument:—A ordinary organ-pipe or cylindrical bell, and is divided into two parts by means of a metallic plate, this forming two chambers in one bell, each with a regulating and adjustable stop, in order to produce, from each chamber, two notes, one a high sharp-toned note, the other a low note. This bell is then secured to a simple cylinder which admits the steam to both chambers, either in combination. The steam being admitted to the chamber on the right hand, gives a high note, and, on the left, a deep bass note, and the steam to act upon both notes in combination produces a loud, peculiar, harmonious sound. The regulating stop can be so adjusted that the high and low notes, when in combination, will produce a discord sound. Distinct notes are also produced by the use of more sounding signal whistles, in combination, each pitched in a different key. The use of this invention consists, not only in the high and low notes in contrast and combination, but the bar or blade acts as a kind of valve, and when the steam strikes upon it, thus causing it to penetrate to a much greater distance than the ordinary whistles can possibly do, the sound being diffused equally in all directions. Also in consequence of the wind acting on the volume of steam, which weakens as well as its force. By this invention several notes can be produced separately, and in combination, by the use of more metallic blades in the cylinder, to regulate them. We will not further draw the attention of your readers by giving marks upon its application, as already stated by eminent authorities upon the subject, as at sea happening on account of the use of sound signals being in use. Our object is this want. The high note may be blown for board, the low note may be blown for stern. These notes made continuous, because they are distinct, its adoption obviates the difficulty now of the coast fog signals being often mistaken for steamers, because the sound produced is so marked and distinct, that it would be impossible to mistake one for the other. This applies to the sound signal-whistle, in combination, and pitched in dif-

ferent keys, gas and electricity. The Court lighted is that known as the "Lord President's" (or the Loan) Court. It is 138 feet long by 114 feet wide, and has an average height of about 42 feet. It is divided down the middle lengthwise by a central gallery. There are cloisters all around it on the ground floor, and the walls above are decorated in such a way that they do not assist in the reflection or diffusion of the light. The absence of a ceiling—the Court being sky-lighted—is to some extent compensated for by drawing the blinds under the sky-lights.

The experiments commenced about twelve months ago, with eight lamps only on one side of the Court. The system was that of Brush. The dynamo machine was driven by an eight horse-power Otto gas-engine, supplied by Messrs. Crossley. The comparison with the gas was so much in favour of electricity, and the success of the experiment so encouraging, that it was determined to light up the whole court.

The gas engine, which was not powerful enough, was replaced by a 14-horse power "semi-portable" steam engine, by Ransomes & Co., of Ipswich—an engine of sufficient power to drive double the required number of lights. The dynamo machine is a No. 7 Brush. There are sixteen lamps in all—eight on each side of the Court. The machine has given no trouble whatever, and it has, as yet, shown no signs of wear. The lamps were not all good, and it was found that they required careful adjustment, but when once they were got to go right they continued to do so, and have, up to the present, shown no signs of deterioration, although the time during which they have been in operation is nine months.

The first outlay has been as follows:—

Engine and fixing, including shafting and belting .....	£420
Dynamo machine .....	400
Lamps, apparatus, and conducting wire ..	384
	<hr/> £1,204

The cost of working has been, from June 22nd to December 31st, during which period the lights were going on 87 nights for a total time of 359 hours:—

	£	s.	d.
Carbons .....	18	9	0
Oil, &c. ....	4	11	6
Coal .....	11	14	0
Wages .....	34	7	6
	<hr/> £69	2	0

being at the rate of 3s. 10d. per hour of light.

Now, the consumption of gas in the Court would have been 4,800 cubic feet per hour, which, at 3s. 4d. per 1,000 cubic feet, would amount to 16s. per hour, thus showing a saving of working expenses of 12s. 2d. per hour, or, since the Museum is lit up for 700 hours every year, a total saving at the rate of £428 per annum.

In estimating the cost as applied to this Court, only half the cost of the engine should be taken, for a second dynamo machine has lately been added to light up some of the picture galleries, and the "Life" room of the Art School. The capital outlay should, therefore, be £594. In making a fair estimate of the annual cost, we should also allow something for per-centage on capital, and something for wear and tear. Take—

	£	s.
5 per cent. on the capital .....	49	10
5 per cent. for wear and tear of electrical apparatus .....	39	0
5 per cent. for depreciation of engines, &c. ....	21	0
Total .....	<hr/> £109	10

#### COMPARISON OF THE ELECTRIC LIGHT.

My disposal would not allow me to make to the economy of the electric light, and to the recent advances made in it March 30th, but some of the facts I am so interested, that I venture to put on paper by this further note. At the ten Museum, very careful observations have been made on the relative cost of the two systems,

leaving a handsome balance to the good of £316 10s. as against gas. The results of the working, both practically and financially, have proved to be, at South Kensington, a decided success.

I am indebted to Colonel Festing, R.E., who has charge of the lighting, for these details.

The same comparison cannot be made at the British Museum, for no gas was used in the reading-room before the introduction of the electric light, but the cost of lighting has proved to be 5s. 6d. per hour—at least one-third of that which would be required for gas. The system in use at the Museum is Siemens's, the engine being by Wallis and Stevens, of Basingstoke.

"An excellent example of economic electric lighting, is that of Messrs. Henry Tate and Sons, sugar refinery, Silvertown. A small Tangye engine, placed under the supervision of the driver of a large engine of the works, drives an 'A' size 'Gramme' machine, which feeds a 'Crompton' 'E' lamp. This is hung at a height of about 12 feet from the ground in a single storey shed, about 80 feet long, and 50 feet wide, and having an open trussed roof. The light, placed about midway, lengthways, has a flat canvas frame, forming a sort of ceiling directly over it, to help to diffuse the illumination. The whole of the shed is well lit; and a large quantity of light also penetrates into an adjoining one of similar dimensions, and separated by a row of columns. The light is used regularly all through the night, and has been so all through the winter. Messrs. Tate speak highly of its efficiency. To ascertain the exact cost of the light, as well as of the gas illumination which it replaced, a gas-meter was placed to measure the consumption of the gas through the jets affected; and also the carbons consumed by the electric illumination were noted. A series of careful experiments, showed that during a winter's night of 14 hours' duration, the illumination by electricity cost 1s. 9d., while that by gas was 3s. 8d., or 1½d. per hour against 3d. per hour. To this must be added the greatly increased illumination, four to five times, given by the electric light, to the benefit of the work; while this last illuminant also allowed, during the process of manufacture of the sugar, the delicate gradations of tint to be detected; and so to avoid those mistakes, sometimes costly ones, liable to arise through the yellow tinge of gas illumination. This alone would add much to the above-named economy, arising from the use of electric illumination in sugar works."

I am indebted for these facts to Mr. J. N. Shoolbred, under whose supervision the arrangements were made.

Some excellent experience has been gained at the ship-building docks in Barrow-in-Furness, where the Brush system has been applied to illuminate several large sheds covering the punching and shearing machinery, bending blocks, furnaces, and other branches of this gigantic business. In one shed, which was formerly lighted by large blast-lamps, in which torch oil was burnt, costing about 5d. per gallon, and involving an expenditure of £8 9s. per week, the electric light has been adopted at an expenditure of £4 14s. per week.

The erecting shop, 450 feet by 150 feet, formerly dimly lit by gas at a cost of £22 per week, is now efficiently lit by electricity at half the cost.

I am indebted for these facts to Mr. Humphreys, the manager of the works.

The Post-office authorities have contracted with Mr. M. E. Crompton, to light up the Post-office at Glasgow for the same price as they have hitherto paid for gas, and there is no doubt that in many instances this arrangement will leave a handsome profit to the Electric Light Company. They are about to try the Brockie system in the telegraph galleries, and the Brush system in the newspaper sorting rooms of the General Post-office in St. Martin's-le-Grand.

W. H. PARNER.

## OBITUARY.

**Earl of Caithness.**—James Sinclair, 14th Caithness, whose death at New York, on *Moz March*, has been announced by telegram, on the 16th December, 1821, succeeded his father and was created Baron Barroigill in the Peer United Kingdom, in 1866. He was elected to the Society of Arts in 1851, and was Vice from 1863 to 1867. He obtained his Fellowship Royal Society in 1862. Lord Caithness, many introduced on his estate in Caithness, a local working on ordinary macadamised roads; he also some railway points of a new description. His genius was likewise displayed in a new for washing railway carriages by mechanical means an improved compass of great steadiness; a tape loom, by which a weaver might stop at shuttles without interfering with the action of the loom. He was skilled in photography, and received a landscape at one of the exhibitions held in the days of the photographic art. At his seat, 8 park, near Welwyn, he had two rooms fitted with photographic and engineering appliances, for mental purposes. His lordship had the in making an extended American tour, but was on board the steamer, and died from exhaustion at the Fifth Avenue Hotel, New York, shortly after.

## NOTES ON BOOKS.

**Notes of Observations of Injurious Insects**  
1880. London: W. Swan Sonnenschein, 1881.

This report, which contains the result of Mr. Ormerod's researches on this subject, contains matter connected with the visitation and insect pests, and its general circulation among gardeners is likely, in some measure, to the extirpation of many of the most destructive. The weather and atmospheric conditions generally under review, Mr. Ormerod shows that of 1880 was remarkably suitable for vegetable by its alternations of dry and sunny weather, storms or periods of rainfall to press on the from most of the localities where the weather thus favourable there are also returns of the amount of insect injury. The great insect attack was that of the larvae of the *Tipula clavicornis*, known as the daddy longlegs. The carrot flies were also very destructive. As an illustration of the amount of cold the grubs of insects it may be mentioned that some grubs of long-legs were frozen by artificial means at Kew Observatory down to a temperature below zero, or 42° of frost, and that all the grubs died under the experiment. It showed that, exceptionally, the grub could even this amount of cold, to all appearance. As a further proof of this, one observer in instances where the grubs have been frozen were quite brittle, and upon being thawed lived as ever. An experiment as to the effect of salt is recorded, in which a number of cabbages planted in flower-pots, all the plants being in thriving state before the grubs were put in them. "Salt was then applied upon the plants, and the quantity increased until the plants were killed."

1; and, on examination, the grub was found at depths in the soil, this depth below the seeming to be regulated by the amount of salt but all the grubs were found to be in no way so for the application." Soaking in strong brine for four hours has been tried, but it has not succeeded; and shortness of food also for a long time has not to have but little effect upon them. One states that he placed some of them in a glass with a little soil, but no plant food, and three after they appeared all right. The one that seems fatal to them is drought. The moth (*Abrax as grossulariata*), and the gooseberry fly (*Nematus Ribesii*), were very plentiful and destructive to gooseberry bushes. Regarding the first, picking the caterpillars off by hand is a mode of effecting a riddance. This, however, in gardens, is a tedious operation, and powdered sulphur, scattered over bushes after thoroughly wetting them, as to make the powder stick, is recommended as an easily applied remedy." It is necessary, however, to see that the berries are carefully washed after using, as the powder is a dangerous poison. Gishurst compound is also recommended. Plans are recommended by different observers for the extermination of the saw fly, one of which is to use pieces of woollen cloth to be laid among the bushes, and to deposit her eggs on them, and by removing them, they can easily be destroyed. Another plan is to water the bushes with warm water in the spring, and to be taken not to have the water too warm to be young foliage. The best plan, however, is to be to remove the soil to the depth of two inches from the bushes in the early spring, and to give a good dressing of lime round each bush; by this means the grubs are cleared away and destroyed.

## GENERAL NOTES.

**ma in Jamaica.**—From a memorandum of Mr. A. Director of Public Gardens and Plantations in (dated January 31, 1881), it appears that, in the month of 18th August last, many thousands of cinchona were blown down and uprooted. In consequence, it is necessary to resume barking operations in spite of the badness of the season. The bark was cured with such success that the whole consignment, consisting of 180 bales, weighing in the aggregate 14,397 lbs., was ready for export within a few weeks of the occurrence of the hurricane. The total results of the cinchona sales during the last month now show a gross return of 41,696 pounds sterling as having been shipped, yielding a total value of 10s. 8d.

**Immigration.**—It appears from Mr. Giffen's report, that the excess of emigrants to, over immigrants from, the countries in 1880 was as follows:—United States, 1,000; British North America, 16,214; Australasia, 11,000; other parts, 5,995. Compared with the previous year, the increase to the United States alone was 68,000, and the reduction to Australasia was more than 50 per cent. The figures of the previous year. In 1878 and 1879, the excess of emigrants over immigrants was 60 and 70 per cent. of the whole excess of immigration. In 1878 it was less than 10 per cent. of the whole. There left our shores for the United States, 108,1 English, 14,471 Scotch, and 83,018 Irish; for British North America, 13,541 English, 3,221 Scotch, and 1,000 Irish; for Australasia, 15,176 English, 3,059 Scotch, and 1,000 Irish; for all places, English, 14,047, Scotch 1,305, and Irish 1,000. The grand total is 227,542 compared with 1879. Including foreigners, 332,294 individuals, 261,560 as steerage passengers, and 50,734 as cabin passengers. Of the former 156,150 sailed from London, 28,056 from Glasgow, 19,068 from other English ports, 3,944 from Glasgow; and 53,944 from Londonderry, all of whom went to the American Continent, in 1880, of 17 to the Republic to one to the Dominion.

**Gold Production of the World.**—The recent report of Mr. Burchard, Director of the Mint in the United States, contains a résumé of the production of gold and silver for 1879 and the two previous years. The total yields were:—

	Value.	
	Gold.	Silver.
1879 .....	105,385,697 dols.	81,037,220 dols.
1878 .....	119,031,085 "	87,351,497 "
1877 .....	113,947,173 "	81,040,665 "
Total....	338,343,955 "	249,429,382 "

Or a grand total for the three years of 587,773,337 dollars, or about £146,943,000. The yield of gold and silver in the United States during 1879 was nearly equal, being 38,899,858 dollars of the former, and 40,812,132 dollars of the latter. Australia comes next, with a production of 29,018,223 dollars, all in gold, and she is closely followed by Russia, which furnishes a tolerably uniform annual supply of about 27,000,000 dollars of gold, though but a small quantity of silver. The Mexican yield is almost entirely silver, value 27,000,000 dollars. There has been a considerable falling off in the coinage of the world during 1879 to that of the previous years, the coinage of 1879 being in value 207,287,384 dollars, while in 1878 it was 349,578,524 dollars.

**Cardamom Cultivation.**—The cultivation of cardamoms is, according to Mr. Markham, carried on to a great extent on the western slopes of the Coorg Mountains. In the month of February, the Coorgs start from their villages, and arriving on the mountain slopes, select one of the largest trees, giving a preference to those on a western or northern slope. Around this selected tree they raise a platform, and commence to fell it. In felling it, they take care that it shall fall towards the base of the slope, and thus, in its fall, carry all before it. Having cleared a space of some 300 ft. long by 40 ft. broad, and freed it from all brushwood, they commence planting. In three months the plants begin to appear; after about 20 months, the plants have reached a height of five feet, and in six months later, that is 26 months after the first sowing, the first clusters of flowers begin to appear. During this period the ground is kept constantly cleared of all weeds. Six months (October) after flowering, the first crop is ready for picking, but a full crop is not obtained till the following year. These plantations are kept up for six or seven years, when the soil having become exhausted, fresh ground is again cleared. The harvesting is attended with some amount of suffering, as the grass which springs up around the cardamom plants cuts like a knife, and large leeches are very abundant. The capsules, when picked, are packed in bags and carried to the villages, a distance, frequently, of ten to twelve miles. Some families have been known to collect cardamoms to the value of 600 to 1,000 rupees per annum.

**Petroleum in Venezuela.**—A remarkable deposit of petroleum is described by the American Consular Agent at Maracaibo as existing between the Rio Tara and Zulua. Near the former, there rises a sand-bank about 35 yards in extent and some 10 yards in height. On its surface is visible a collection of cylindrical holes, apparently artificially made, and of different diameters, through which streams of petroleum, mixed with boiling water, gush out with great violence, accompanied with a noise as though two or three steamers were blowing off steam. The column of vapour that ascends from it would doubtless be seen from a long distance, were it not shrouded by the thick forest, to which the petroleum beds that evidently lie underneath give a perpetual greenness and freshness of foliage. Dr. M'Gregor states that from one of these holes, notwithstanding the difficulties of the position, he filled, in 42 seconds, a vessel containing 15 bottles, or as fast as four gallons per minute, or 240 gallons per hour, or 5,760 gallons during the 24 hours. A curious phenomenon has been occasionally seen in Venezuela ever since the conquest, consisting of a frequent lightning, without any explosion, which is observable from the bar at the entrance of the Lake of Maracaibo, close to the island of Bajoseco, and which Colonel Codazzi, in his geography, attributes to the vapour ascending from the Cienega de Agua Caliente. This appearance, called by the mariners, "El farol de Maracaibo," is more probably due to the inflammable gas that permeates the whole district to such an extent that it is known by the natives as El Inferno. There is no doubt that the supply of petroleum is very abundant not only here but in the neighbouring Republic of Columbia, where, between Escuque and Betijoque, the

labourers gather it up in handkerchiefs, which, when saturated, are squeezed out into barrels.—*Times*.

**Hours of Labour in French Manufactories.**—The following are the regulations as to work in factories definitely proposed to the French Chamber:—Art. 1. The duration of work in factories and workshops must not exceed ten hours a day, or six days a week. 2. Nightwork (between 9 p.m. and 5 a.m.) is forbidden in these establishments so far as women are concerned; but, in the event of stoppage resulting from an accidental interruption, or *force majeure*, the above restriction may be temporarily removed, for a given period, by the local committee or the inspector appointed by the law of 1871. 3. Government regulations will determine the exceptions to the provisions contained in Arts. 1 and 2 on account of the nature of the industries, &c. 4. Any manufacturer or manager acting in opposition to the present law and the Government regulations will be proceeded against, and punished with a fine of from 16 to 20 francs. The fine will be enforced as often as persons are employed in a manner contrary to law, provided that the total amounts do not exceed 500 fr. (£20). On a second conviction within twelve months of the former, the delinquents shall be liable to a fine of from 50 to 500 fr., provided that the total sums do not exceed 1,000 fr. (£40). 5. The local committees and inspectors of children's work in factories appointed by the law of 1874 are charged with the application of the present law, which (6) repeals that of 1848.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

APRIL 27.—“Five Years' Experience of the Working of the Trade Marks' Registration Acts.” By EDMUND JOHNSON.

MAY 4.—“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MAY 11.—“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works).

MAY 18.—“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS.

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGAERTH.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

APRIL 28.—“Impurities in Water, and their Influence upon its Domestic Utility.” By G. STILLINGFLEET JOHNSON, F.O.S.

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Prof. A. K. HUNTINGTON.

MAY 26.—“Telegraphic Photography.” By SHEL-FORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

### INDIAN SECTION.

Friday evenings, at eight o'clock:—

APRIL 29.—“The Building Arts of India.” By General MACLAGAN. ANDREW CASSELL, Member of the Indian Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

### CANTOR LECTURES.

Monday evenings, at eight o'clock:—  
The Fourth Course will be on “The making,” by ALAN S. COLE. Four Lectures.

#### Syllabus of the Course.

#### LECTURE II.—APRIL 11.

Needlework upon a material. Needlework rate threads. Venetian needle-point lace point and tape lace. French needle-point centres. English and Flemish needle-point.

#### LECTURE III.—MAY 2.

Fringes. Twisted thread-work in the 15th century. Early designs for plaited threads. Italian, Flemish, French, and English lace. Laces of primitive design.

#### LECTURE IV.—MAY 9.

Resumé as to styles of design in hand. Traditional patterns. Sketch of the developments for knitting and weaving thread lace. Differences between machine and hand laces. Modern hand-made laces at Buxton, Honiton, &c.

This course will be illustrated by special diagrams and photographs enlarged with means of the lantern and oxyhydrogen light.

The Fifth Course will be on “Colours and its Influence upon Various Industries.” By R. BRUDENELL CARTER, F.R.C.S. The course will be illustrated by special diagrams and photographs enlarged with means of the lantern and oxyhydrogen light.

May 16, 23, 30.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,482. Vol. XXIX.

FRIDAY, APRIL 15, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.O.*

## NOTICES.

## CANTOR LECTURES.

second lecture of the fourth course was on Monday, 12th inst., by ALAN S. COLE, "Art of Lace-making." The lecturer treated needlework upon a material, needlework on waste threads, and the various kinds of lace. The third and fourth lectures were on May 2 and May 11 respectively.

## EIGN AND COLONIAL SECTION.

April 5, 1881; JOHN RAE, M.D., F.R.S., &c. The paper read was on "Canada: Colony and the new Dominion." The paper will be printed in the next number of the

## BUSINESS OF THE SOCIETY.

## CHEMISTRY AND PHYSICS SECTION.

March 24, 1881; LATIMER CLARK, F.R.S., in the chair. The paper read was on—

## FUTURE DEVELOPMENT OF ELECTRICAL APPLIANCES.

Lecturer John Perry, B.E., Assoc. M.I.C.E.

It has been my intention to introduce this subject to your notice by speaking of the great progress of electrical science has already done for us. I assure you, that I had arranged a paper on this subject, touching on Galvani, and Newton, and Boyle, and Watt, and Joule, and Thomson, showing how these men in their laboratories who have paved the way for Stephenson, Wheatstone and Morse, Hughes, Edison, and Graham Bell.

I meant to tell you how, in days gone by, a few Birmingham business men subscribed to give their townsman, Priestley, sufficient money to live upon while working at original research; and I felt able to prove so clearly to you, that it was for the good of the nation to provide scientific men with large laboratories, and to ensure them freedom from ordinary cares, that in the mere preface to my proper subject, I prepared an hour's lecture. Luckily, I remembered that you had all had opportunities of hearing about the benefits you owe to science; and I bethought me that you might even be tired of listening to truisms regarding endowment of research; truisms to members of the Society of Arts, but not so well believed in by the general public, and especially by that section of the general public which sees reason to lean on Mr. Ruskin, in whose nostrils the mere names of Watt and Stephenson are as the savoury odours of the Thames at low water, and attends to the views of Sir John Ellesmere, who hated telegrams more than he disliked our common enemy. Men of this stamp may well think of the future with horror, for there is every sign that applied science is increasing the acceleration of the rate of its development. To such men I would say—Put a stop to laboratory work; set your faces against the endowment of research; root up the acorn if you would not in the future be plagued with the oak. The applied science of the future lies invisible and small in the operations of the men who work at pure chemistry and physics. These men do not know what will be the outcome of their labours. They often think that they sympathise with Mr. Ruskin; but you might as well ask a dram-drinker to give up that which his soul loveth, as ask a man who has done real experimental work to give it up. I have often watched Sir William Thomson, to whom every object in nature is continually suggesting new ideas, new experiments; to whom every particle of brass scraped off by a file is a being full of complication, an object of interest, and a thing of beauty, and to whom the study of the bending of a bit of brass wire is a joy for ever. Sir William Thomson believes in applied science, but such belief has really nothing to do with the delight which he and every other experimenter has in his work.

Now, electrical science has reached a position from which, on every side, hundreds of enticing paths lead forward into unexplored regions of nature. At every step in advance, the laboratory worker sees to right and left of him new and promising lines of research; and he feels that, for the work to be done, the present army of explorers is all too small and weak. But interesting as it might be to prophesy on investigations newly begun, it is rather my purpose, to-night, to take you upon the well-trodden ground prepared for us by Faraday, and Joule, and Thomson, to show you how, in one or two great lines of the applied science of electricity, certain fixed laws tell us about the future. I shall then speak of a few of the more recent discoveries.

Now, in the first place, you must remember that electricity is, to us, something that can be measured; although, unfortunately, to the ordinary telegraph operator, this is not the case. If you can imagine a mechanical engineer regarding

a distance of a few inches as being equal to the distance of a few miles, or even of a few thousand miles; if you can imagine a grocer to confound an ounce of sugar with a ship's-load of the same material, you get a too truthful idea of the vagueness, the general want of definiteness, in the notions of nearly all students of this subject until a few years ago, and, I am sorry to say, that much of this vagueness is still to be found even in modern scientific papers. Perhaps, when electricity is supplied to every house in the City of London at a certain price per horse-power, and is used by private individuals for many different purposes, this vagueness will finally disappear.

To get exact ideas in any department of physics, we have one firm foundation to build upon, viz., that a certain amount of energy or power of doing work remains always the same, in whatever form it may appear. I have here various sources of electricity—a voltaic cell, a thermopile, a glass-plate machine, a magneto-electric machine, which may be turned by hand, and two dynamo-electric machines outside, which I can drive by means of a steam-engine. As you know, there are many others. To all these, some form of energy is given, and they convert this energy, badly or well, into electric energy. The cell burns zinc; in the thermopile gas is burnt; to the three last machines mechanical energy is given; they all give out electrical energy. Now, how do we know that there is a production of electrical energy? Let us take any one of them (this voltaic cell, for instance). Some form of energy is given out, for you see that I can convert it into heat. (Experiment shown.) Here I take advantage of a property somewhat analogous to mechanical friction.

This thermopile is also generating electricity. To test this I connect its poles to the wire of a galvanometer, and the instantaneous deflection of the needle of the galvanometer tells me about the current. (Experiment shown.) Here is another proof that some kind of energy is traversing the wire connecting these two screws. The two wires are attached to an arrangement at the other end of the room; when I complete the circuits, whether I do it here or there, the bell rings. (Experiment shown.) You see that in this case the heat energy given out by this burning gas is converted partly into electrical energy, in which state it can be transmitted to a considerable distance, and there converted into mechanical energy, or into sound, or into any other form of energy. In these and other ways we can detect the existence of the electrical energy coming from all these generators, and measure its amount. Now, Joule's experiments tell us that any generator gives out exactly as much energy as is given to it, but much appears in the form of heat. All these generators get heated, and may be said, therefore, to waste energy. One great object of the inventors of such machines, is to give out as much as possible of the energy supplied to them in the shape of electrical energy. You must clearly distinguish between electricity and electrical energy. A miller does not merely speak of the quantity of water in his mill-dam; he has also to consider the height through which it can fall. A weight of one thousand pounds falling through a distance of one inch represents the same energy, that is, gives out the same amount of work

in falling as one pound through one inch. A mere statement, then, of the quantity of electricity given out by a machine is not sufficient; it is also necessary to state what is the difference of potential through which it falls. The quantity of electricity in a thunderstorm is comparatively small, but the difference of potential through which this quantity passes when it occurs is exceedingly great. So it is with the dynamo. The quantity of electrical energy developed by a glass machine. The quantity of electricity available from this machine is comparatively small, but the difference of potential through which it is like a small quantity of water at a very great height, whereas, in all the machines we have, in the analogy of the very great quantity of water and a small difference of level. I put this water before you because you have all more or less notions about water, and because, within limits, the analogy is a very true one. I have traced it more fully in the wall-sheet I.

#### WALL-SHEET I.

<i>We Want to Use Water.</i>	<i>We Want to Use Electricity.</i>
1. Steam pump burns coal and lifts water to a higher level.	1. Generator converts mechanical energy and lifts electricity to a higher level or difference of potential.
2. Energy available is amount of water lifted X difference of level.	2. Energy available is amount of electricity X difference of potential.
3. If we let all the water flow away through channel to lower level without doing work, its energy is all converted into heat because of frictional resistance of pipe or channel.	3. If we let all the electricity flow away through wire from one generator to another without doing work, its energy is all converted into heat because of resistance of wire.
4. If we let water work a hoist as well as flow through channels, less water flows than before, less power is wasted in friction.	4. If we let electricity work a hoist as well as flow through wires, less electricity flows than before, less power is wasted in resistance.
5. However long and narrow may be the channels, water may be brought from any distance, however great, to give out almost all its original energy to a hoist. This requires a great head and a small quantity of water.	5. However thin the wires, electricity may be brought from any distance, however great, to give out almost all its original energy to a hoist. This requires a great difference of potential and a small quantity of electricity.

You will readily understand them if you will remember that for all purposes it is necessary to have energy in the shape of a small quantity falling through a great difference of potential; and for other purposes a great quantity falling through a small difference of potential. When electricity falls through a difference of potential, this difference is called motive force. It would take me too long to explain to you why we use two terms to express the same thing; but briefly "difference of potential" is analogous to "pressure" or "head" of water, and "motive force" is analogous with the difference of potential. A slowly moving piston

an unfortunate miller to produce his fly.

object of my paper is to show youicians have very definite ideas on theey are working at; that the measure-which their work depends, have exactnd that there is hardly any problem inan's powers which you can set beforeve which they may not hope to do withcostly apparatus. Everybody knowsil engineer is still very far from havinglimiting lengths or sizes to which largeother structures may be built, at aless cost. Everybody is competent toghly correct judgment in such matters,tybody has more or less correct notionsweight, and strength of materials. Andway that you may be able to guess oflectrician may do in the future, it ishat you get fairly correct ideas ofagnitudes; and the curious fact ishow simple it is to arrive at these, so few people possess them. On theII and III, I have given such help asvisibly in this matter; but time willf my entering into such explanatoryshould desire.

#### III.—RATE OF PRODUCTION OF HEAT, ED IN THE SHAPE OF HORSE-POWER.

of a circuit = current in webers  $\times$   
e force in volts  $\div$  746.

of circuit = current in webers  $\times$  difference  
at the two ends of the part of the  
section  $\div$  746.

e of current in webers  $\times$  resistance of  
ohms  $\div$  746.

e a number of generators of electricity in

a circuit, whose electromotive forces in volts are— $E_1$ ,  
 $E_2$ , &c., and if there are also opposing electro-motive  
forces,  $F_1$ ,  $F_2$ , &c., volts, and if  $C$  is the current in  
webers,  $R$  the whole resistance of the circuit in  
ohms,  $P$  the total horse-power taken in at the gene-  
rators,  $Q$  the total horse-power converted into some  
other form of energy and given out at the places where  
there are opposing electromotive forces,  $H$  the total  
horse-power wasted in heat, because of resistance,  
then—

$$C = \frac{(E_1 + E_2 + \&c.) - (F_1 + F_2 + \&c.)}{R}$$

$$P = \frac{C}{746}(E_1 + E_2 + \&c.); \quad Q = \frac{C}{746}(F_1 + F_2 + \&c.);$$

$$H = \frac{C^2 R}{746}$$

The lifting-power of an electro-magnet of given  
volume is proportional to the heat generated against  
resistance in the wire of the magnet.

The future of many electrical appliances depends  
on how general is the public comprehension of the  
lessons taught by these wall-sheets. If a few  
capitalists in London would only spend a day or  
two in learning thoroughly what they mean, I am  
quite sure that electrical appliances of a very  
distant future would date from a few months  
hence.

It is not necessary for me to tell you now that  
electrical energy may be produced. Nor need I  
waste time in speaking of how it may be trans-  
mitted to a distance by means of insulated metal  
wires. A more important fact is that, when  
electricity is flowing in a wire, I can transform  
part of its energy into other shapes. For instance,  
here is an iron wire of 2 ohms resistance. Suppose  
this to be in a cold room, and I turn on the elec-  
tricity tap. (An electric machine, driven outside by  
a gas-engine, is heremy source of energy.) This wire  
is now getting a supply of electrical energy, and is  
converting it into heat. Mr. Andrews tells me that  
there is now a current of 20 webers flowing  
through the wire, and hence the wire is giving out  
more than one horse-power in the shape of heat.  
Some of you may have thought that very little  
heat can be given out by such a wire; but these  
are the exact figures, and you can all see that they  
represent a pretty large supply. When the current  
has been flowing for a short time, the neighbour-  
hood of this wire will be found unpleasantly warm,  
and I can assure you that the use of this instru-  
ment for certain measuring purposes is very dis-  
agreeable in the summer time. It is hardly  
necessary to say that a wire, through which a  
current is flowing, may be made to give out its  
heat for a great variety of purposes. The temper-  
ature may be pretty much what we please. Thus,  
I turn the tap, and this wire gives off very intense  
heat. (Experiment shown.)

I had asked my friend, Mr. Andrews, to boil  
water for you by means of a hot spiral of wire;  
but he has given us something of his own which  
is very much better. You see that I turn this tap,  
and so pass this current among all these little bits  
of carbon; first we have bright spots of light here  
and there stealing from point to point; then  
these lights fix themselves in definite places, and  
round them the carbon gets red hot, until we get  
in two minutes the most perfect form of fire for

heating a room or boiling a kettle that I have ever seen. I have in vain tried to get Mr. Andrews to exhibit before you to-night his exquisitely simple plate electric light. I have watched it burning, and know that it has a future before it, if it were only from the fact that it burns steadily for a whole week with a powerful arc light without renewal of the carbons, and yet these carbons might be put in one's pocket, and the lamp thrown about anyhow, without risk of anything getting out of order. The excessive caution of the inventor prevents my showing you this simple little lamp. My own lamp is here before you, but beyond telling you that it is very simple, and that only one magnet is employed in the regulation and separation work, I may not detain you. I now turn another tap, and the strip, through which the current passes, becomes white hot, and we call it, vaguely, an electric light. (Experiment shown.) This is the incandescent light which has been proposed for use in ordinary houses. It is, confessedly, not economical, but it is very convenient for chamber use. I now turn another tap, and you see a powerful Serrin lamp, which I mean to leave burning. You know now that we can convert electrical energy into heat and light; but the question is, how much of a result do we get for the power expended?

Professor Ayrton and his students measure at Cowper-street, 1st, how much gas is being used by his gas-engine; 2nd, how much horse-power is being actually given to his electric machine; 3rd, how much current is produced through external circuits by his machine; 4th, the resistance of these circuits. He can now calculate exactly how much horse-power is expended in any part of these circuits; and also how much light is actually given out by an electric lamp.

I must now try to give you an idea as to how these measurements are made. The very elegant dynamometer employed by our Chairman to measure the power which is being transmitted to a machine, I am not at liberty to describe. The plan devised by Professor Ayrton and myself is capable of being applied at very small cost to existing shafting in factories, so that the power given to any shaft may be known. A is a shaft which is to receive power. B is a loose pulley

FIG. 1.

driven by a belt. C D is a wheel whose rim is fixed to the rim of B; its crooked arms are made of

flexible steel, its boss being key Evidently B can no longer be called if it turns it must cause the shaft the turning moment is accurately certain amount of yielding of the shaft. If this yielding is known, and also horse-power transmitted is also known we copy the principle of General instead of using his elaborate system we simply convert the tangential motion which is visible. This is in various ways, of which the following is simple. A stiff arm, E A, is fixed A; at E and at a point O of the of two light links are pivoted, which together at O, where there is Evidently, if the distance OE becomes much power is being transmitted, 1

FIG. 2.

Another arrangement, giving greater

FIG. 3.

When tangential strain is small, this method is used

in the centre, and therefore the circle of ascribed by it has a greater radius. The amount shown in Fig. 3 is sometimes more exact.

To measure the distance of the bead from the means of a scale supported level with the Other dynamometers, which have till now in use are shown in the diagrams. For measuring very strong currents, such as are in electric lighting, Professor Ayrton and I have devised this "dead-beat" galvanometer. Without going into a detailed description of the instrument, I may mention that it possesses the following great advantages. Only can the strength of any current be read once in webers, but the user can at any time test his own instrument, or graduate it, as technically called, by employing only the current produced by a single Daniell's cell. The result is arrived at by the device of causing weak current to circulate 60 times round the coil, while the strong current only goes round once; a special form of commutating arrangement enabling the very same wires in the galvanometer to serve for both strong and weak currents; comparisons can be made, not merely approximately, but with absolute accuracy, even if the wires are wound on the galvanometer quite closely.

The instrument shown in this diagram may be used in the same manner, as it is also provided with the same kind of commutator. We call it an

FIG. 4.

coiled cable of ten strands, which may be used in "arc" or in "series," by means of the commutator, A, and the spring.

an electric power measurer, because its deflections are proportional to the product of difference of potential between the arc, or incandescent carbon, and the electric light (see wall-sheet II., p. 459). A glance at the horse-power given out at that time. The electro-dynamometers of Dr. Siemens and Mr. Andrews are here before you, and may be used during the reading of the paper to measure the power. Mr. Andrews simply uses a steel-yard to measure the attraction between two coils, when the currents flow in them, when they are at a fixed distance, and he, therefore, like Dr. Siemens, measures the mean square of the current flowing. The instruments have the disadvantage that an

ordinary pair of scales has in comparison with a spring balance, viz., that a sudden temporary change in the thing weighed cannot be measured; but they have the advantage of great accuracy in the measurement of a constant effect.

To measure the light itself in standard candles, the students in the course of electric lighting, at Cowper-street, employ our photometer (Fig. 5), of which three specimens are before you, and there is an enlarged drawing on the wall. The principle

FIG. 5.—DISPERSION PHOTOMETER.

E, electric light.  
C, standard candle.  
S and T, screens of tissue paper.  
G, H, plates of green or red glass.  
 $E = \frac{S \cdot L^2 \cdot L S^2}{O \cdot T^2}$

of old methods of measurement of strong lights was to weaken the intensity of illumination of a screen by taking the screen far enough away. Only in this way could the illumination of the screen by the electric light be made equal to the illumination of a similar screen by a standard candle. Our plan of weakening the light from an electric lamp is not by going forty or eighty feet away from it—for people who deal with electric lamps do not often possess a large enough chamber with blackened walls—but by letting, instead, the light pass through a concave lens. The principle is then exceedingly simple. Mr. Wormell has been making a few measurements whilst I have been talking, and I see that this electric light seen through green glass has varied from 2,214 to 2,136 candles in the last three minutes. Sir William Thomson suggested to us to make two measurements, one through green and the other through red glass, for reasons which must be obvious. Anyone who may wish it will have an opportunity of measuring the power of an electric light for himself after the lecture.

From all this you will see that perfect methods exist for measuring the power which is being given out as heat or light in any part of a circuit, as well as the power given to the electrical machine. In fact, we have a perfect measure of what is called the efficiency of our arrangement.

It is hardly necessary to tell you that every house and every street may be lighted electrically. Into the proof that, in the future, are lamps of thousands of candle power at elevations proportional to the square roots of their powers, will be used for large spaces, and that incandescent lamps of only hundreds of candle power are suitable only for private houses; into a consideration of these statements I shall not enter, because Professor Adams is dealing with the question in his Cantor lectures. You all, in one way or another, feel that electric lighting is a foregone conclusion. But, perhaps, you were not aware that buildings may

be heated by electricity. The neighbours of this iron wire will say that it gives out a considerable quantity of heat, but whether the heating may be performed economically will depend on the story told us by the measurements which have been made. Now let me turn my tap again. I let my current pass through this insignificant little dynamo machine, and you observe that it is in motion; not only is it in motion itself, but it is driving this lathe. A machine is receiving mechanical energy outside, it converts this into electrical energy, which is conveyed by wires into the room and to the machine before you, where it is converted into mechanical energy again. I think I shall never forget the astonishment of a workman in Sheffield, who had put up a saw-bench for use at Professor Ayrtton's lecture, and who was about to rehearse his part. He looked at the motionless saw, he had his hand on the wood, he saw there was a belt from a little mite of an electric machine, two wires dangled from the ceiling to the machine, and this was all. What notions of being played with came into his mind I do not know, but when, at the distant place, a water-engine was started to drive the distant machine, when the saw set off nearly at its full speed, and the two dangling wires were evidently the only methods of communication, this thoughtful workman's face expressed in full perfection the absence of all his reasoning powers. I do not wish you to lose your reasoning powers, but it is necessary that you should get thoroughly impressed with the notion that the power to drive this lathe is actually being transmitted through these limp and motionless wires.

I should like to be able to hold that machine motionless, and to prove to you that the current flowing through the wires is immediately diminished when the machine begins to move. In fact, I want to show you that this machine produces an electromotive force, which is in opposition to that of the distant machine. You see that we are just able to hold it, and now I am informed that the current flowing is 19.5 webers, whereas if we let it run, and drive the lathe and the sewing-machine and this fan, you will find that the current is diminished. It is 11.2 webers, or about half what it was before. It is not necessary to give you further examples of this transmission of power by electricity, but on account of the evident importance of the matter to the health of the community, I will give you one more, and I turn the tap, and you all see that the insignificant little machine is driving a ventilator. This ventilator might be used in a chimney in the summer time when fires are not in use, or in any suitable outlet from rooms; and pray remember that mechanical ventilation is ever so much more efficient than what is called natural ventilation, in which advantage is taken of the lightness of warm gases.

Now, what do these examples show you. They show that if I have a steam-engine in my back yard, I can transmit power to various machines in my house, and if you measured the power given to these machines, you would find it to be less than half of what the engine driving the outside electrical machine gives to it. Further, when we wanted to think of the heating of buildings and the boiling of water, it was all very well to speak of the conversion of electrical energy into heat, but now we

find that not only do the two electrical get heated and give out heat, but heat is by our connecting wires. We have the side our most important question. energy can be transmitted to a distance to many thousands of miles, but can it formed at the distant place into mechanical other required form of energy, nearly amount to what was supplied? Unfortunately must say that hitherto the practical answer to us by existing machines is, "No; always a great waste due to the heat above. But, fortunately, we have the measurements of which I have already the facts given us by Joule's experiments formulated in ways we can understand. facts tell us that in electric machines of and in their connecting wires, there is heating, and therefore little loss. We believe, at no distant date, have great stations, possibly situated at the bottom, where enormous steam-engines enormous electric machines. We shall laid along every street, tapped into as gas-pipes are at present; we shall quantity of electricity used in each heated, as gas is at present, and it will through little electric machines to drive to produce ventilation, to replace fires, to work apple-parers, and machine barbers' brushes, among other things, to give everybody an electric light.

Probably you think it very strange to show you the inefficiency of electricity of energy, and then make this very bold Well, the fact is, that the ordinary machines in use have not been constructed view to economy. They have been constructed show that brilliant lights and considerable may be produced from small machines have, at a comparatively small cost attention to the fact that electricity is a agency. In so far they have done well the other hand they gave rise to the assumption that 50 per cent. of the power given to the generator, was a small amount which could be taken motor. The true solution of the transmission of power was, I believe, by Professor Ayrtton in his British lecture at Sheffield. It had been suggested to transmit the power of Niagara Falls by a copper cable of enormous thickness needed. Mr. Ayrtton showed that power might be transmitted by a fine wire if it could only be sufficiently well insulated also showed that, instead of a limiting 50 per cent., the one thing preventing the whole of our power was the mechanical which occurs in the machines. He fact, how to get rid of electrical friction briefly give you our reasons. A Niagara receives mechanical power, and electricity. Call this the generator, and that wall-sheet III teaches us that the power is proportional to the electromotive produced in the generator, multiplied current which is actually allowed to there be wires to another electric machine New York, which will receive electricity, and

ical work, as this machine does here. Now, a little while ago, that this machine, may be called the motor, produces a back electromotive force, and the mechanical power is proportional to the back electromotive multiplied into the current. The current, of course, the same at Niagara as at New York, is proportional to the difference of the two electromotive forces, and the heat wasted is proportional to the square of the current. You see in wall-sheet III, that we have the proportion—power utilised is to power as the back electromotive force of the generator is to the difference between electromotive of generator and motor. This reason is only and yet very exactly given in wall-sheet IV.

## WALL-SHEET IV.

Let the electromotive force of generator be  $E$ ; of motor total resistance of circuit be  $R$ . Then if we let  $Q$  be the horse-power received by the generator at the motor,  $Q$  the horse-power given out by motor at the generator,  $H$  the horse-power heat in machines and circuit.  $C$  the current through the circuit.

$$C = \frac{E - F}{R}$$

$$P = \frac{E(E - F)}{746 R}$$

$$Q = \frac{F(E - F)}{746 R}$$

$$H = \frac{(E - F)^2}{746 R}$$

$$Q : H :: F : E - F$$

Let us say more shortly still, the power wasted is proportional to the square of the current flowing, the power utilised is proportional to the current, and also to the electromotive force of the generator. The greater, then, we make the electromotive force, the less is the loss of power in the circuit. Perhaps you will see this better in the water analogy. A small quantity of water flowing through a water-main, may convey a great amount of energy, if it only has sufficient head, but depends very much on the frictional loss of power is independent of the head, but depends very much on the velocity of water. In the model before you is the water analogy. (Experiment shown.) A reservoir, kept filled with water by a pump, which draws the water from the sea. Water flows from reservoir A to the turbine, B, where it drives a turbine giving due to its head,  $BK$ . The current from the turbine through the communicating pipe, is the same, so long as A and B are at the same level, and therefore the frictional loss of energy is always the same, whereas the power is increased from B, by driving the turbine, in proportion to the height of B above sea

level, then, to which the above laws led us. Ayrton and myself saw that for the development of the transmission and distribution of electric energy it will be necessary to use machines of great electromotive force. So important must this principle be-

come, that we believe there is a future in this direction for the employment of plate electrical machines, such as that of Holtz. Now the electromotive force of an electric machine may be increased in three ways:—1. By increased speed, as you easily see when I turn this magneto machine more rapidly. 2. By increased strength of magnetic fields. 3. By increasing the length of wire on the moving armature. Of these methods the first is most important. Now, if iron is used in the armature, since it is magnetised and demagnetised very rapidly, its coercitive force prevents this magnetisation and demagnetisation being as complete at the high speeds I contemplated as it is at the ordinary speeds of the present day. I say this in spite of the fact shown by some unpublished experiments of ours, which imply that the magnetisation and demagnetisation of a bundle of fine soft iron wires are as complete when effected sixty times per second as when effected once per second. Besides this, a very considerable quantity of heat is developed in such rapid magnetisation and demagnetisation as does occur. The electric machines of the future will, I am convinced, be without iron in their movable parts. High speeds necessitate careful construction and the balancing of moving parts, and great attention being given to rubbing surfaces. By rubbing surfaces, I do not merely mean the bearings of the machine, but the commutator, which is rubbed by the collecting brushes. Much of the waste of energy by mere mechanical friction which occurs in electric machines occurs at the brushes; but, hitherto, other waste has been so great that this might be neglected as unimportant. But it is very important in the machines of the future. The loss of energy by friction is proportional to the number of revolutions per minute, and to the diameter of the rubbing surface. I have given considerable thought to the reduction of this friction, and have arrived at a form of commutator shown at A in the diagram (Fig. 4), which largely diminishes the loss. The parts of the commutator must be firmly fixed, but they must also be well insulated from one another, therefore they must be separated by some rigid insulator, such as ebonite, at the places where they are screwed up; hence they are necessarily far apart at these places. If they are rubbed at these places, however, there will be a great loss of power in friction, and hence they ought to be bent in towards the axis of rotation, where they may be insulated from one another by narrow air spaces, and where they may be rubbed by the brushes, with only a small waste of energy. This plan I have proved to be quite feasible. In the larger machines of the future, its importance will become much more manifest than it can be in existing machines. This frictional principle is illustrated by the model before you. Here are two surfaces, making the same number of revolutions per minute. If the same amount of rubbing occurs, you observe that when I rub the surface of larger diameter, there is great loss of energy, and the motion is stopped; whereas, when I rub the surface of smaller diameter, there is only a small loss of energy, and the motion is not stopped. (Experiment shown.)

This necessity for a great velocity of moving

coils past fixed magnets, necessitates increase of size of the armature, because for a given velocity the centrifugal force tending to burst the revolving armature is inversely proportional to the radius. For instance, here are two light wheels, made in exactly the same way. You can examine their construction at the end of the meeting. They are rotated at a different number of revolutions per minute, so that the actual velocities of their rims shall be the same. You observe that the rim of the smaller bursts in pieces, and the larger is unburst.

There is another important reason for increased size, namely, that of similar dynamo machines, one giving out eight or more times as much energy for the same number of revolutions per minute, the larger would delay me too much to go into this question of size fully; but if it be remembered that the electromotive force of each moving coil is proportional to its area, then, without taking into account, increase of strength of magnetic field, which certainly occurs with larger machines, we get eight times as much effect for double the size. Electric machines of the future will then, probably, be of great size, moving with exceedingly great velocity.

The third method of increasing the electromotive force by having greater lengths of wire in the armature is always available, but inasmuch as every increase so produced causes a proportional increase in the resistance of the circuit, and therefore a waste by heating, this method is not quite so economical as the increase of speed method.

It is to be remembered that the lifting power produced in an electro-magnet of given size is simply proportional to the heat produced in the wire on the magnet, and if it is our object to diminish this heat, we must discard all idea of working the magnets of electric machines by their own currents. In fact, the function of dynamo machines, like these I have been using, will, in the future, be to feed the magnets of larger machines, which will give place altogether to magneto-machines. I have now given you, very briefly, the principles of the dynamo machine, which have occurred to me.

However, be quite mislead- ing in this wall-sheet are correct- and- But if the practical transmission of all kinds of light and machine power to all parts of London from a single centre, and a return to that old state in which the great numbers of men in large manufactories were possible to dispense with the congestion of the city, I need hardly tell you that best thing to be looked forward to with anxiety. I need hardly tell you that best thing to be looked forward to with anxiety. I need hardly tell you that best thing to be looked forward to with anxiety.

I have been dealing with the principles, and electricians will take various things to carry out the idea put before you. In my machine, exhibited here, and also drawn upon diagram (Fig. 6), I have endeavoured to carry out the idea.

FIG. 6.—PERRY'S DYNAMO MACHINE.

made herself comfortable, and has added wealth. Adding to her wealth is an accident, perhaps, but adding to the happiness of the poorest people in this cradle of the Saxon race is certainly the most important to be effected by the wealth of England this, through the agency of electricity, is a bad financial investment.

This very large subject, let me speak of the applications of the above principles for a future before them. The development of the telephone and of telephone exchanges, any person in London can speak directly to any other Londoner, and, indeed, with any person in the country; this, as you all know, is a settled matter, although, no doubt, a little difficulties still to be surmounted. In the case of a telephone wire there is a generator, an electro-magnetic machine, which receives sound and gives out electricity. At the other end there is a receiver or motor, another such machine which receives electric energy and gives it out. We have, in fact, a simple example of the most economical examples I know of the transmission of power by means of sound. Quick speeds caused by vibrations of several hundred times per second, and strong magnetic fields, have produced this wonderful effect which enables men in Paris to speak to persons of their family in Marseilles. Again, the use of electric railways is a part of the present subject which I have already dealt with. I propose you all know the general principle of electric railways as hitherto constructed. Only to observe large effects produced, the first is now working before you would give an example of future constructions of this kind in a railway, or the one to be exhibited [In this experiment a circular railway is run from a magneto-electric machine in my hand.] A generator of electricity is a large stationary engine, somewhere in the neighbourhood of the railway. A motor engine receives electric energy by the conductors, and converts this into mechanical energy to drive the carriage. Even the small experiments of Dr. Siemens show that there can be no doubt that the introduction of electric railways everywhere is merely a question of time and the sacrifice of much existing plant.

Of proof was very much needed by the electrician sees much further; after insulation for the conductor, and of the above principles to hundreds of miles of rail instead of a thousand yards; in fact, that the larger the experiment, the more must be its success. He looks forward to the sense of a vitiated atmosphere in our roads and railways. He sees that the weight of the train will be no heavy locomotive engine; each carriage will have its own engine and braking machinery, and the cost of fuel and wear and tear of permanent way will become less than one-quarter of what it is at present; he sees, in fact, all the things that will arise, when, instead of making the train-engine travel backwards and forwards in the carriages, the carriages alone travel, and the train-engine is not near the railway at all, at once, also, all the energy at present

wasted in stopping a train, will simply be given back to the generator.

I have mentioned electric lighting, and telephones, and railways, because I know that many of you must have expected to hear of them, but I mainly wish you to consider these appliances as examples simply of the transmission of power by electrical means. In the same way I might refer to a countless number of other appliances, giving you a mere catalogue of them; but, from the ordinary house-bell to the complicated arrangement by which my brother regulates the weirs on a river to prevent floods; from the time-regulating luxury of certain clockmakers, to the quadruplex telegraphy of Muirhead and Winter, they are simply methods of transmitting energy by electricity, and as such, their economical development depends on the recognition of the above principles. Take, for example, the case of ordinary telegraphy. There can be no doubt that it is absurd to fill large houses with tens of thousands of voltaic cells to work telegraph lines. But it is not sufficient for the Post-office authorities to feel the annoyance, and merely try to replace batteries with such a machine as you see before you—a machine of but one ohm resistance, while every mile of telegraph wire may have twenty ohms resistance. I am sure that everybody belonging to the telegraph department will be satisfied with a change that gives them one dynamo machine for all those thousands of sloppy voltaic cells; and there is no longer any excuse for further delay, since Mr. Schwendler has been perfectly successful in working long telegraph lines in India in this very manner.

When we think of electricity as an agent by means of which energy may be transferred and altered, it is natural to ask if, by means of it, energy can be stored up. If we could obtain an efficient method of storing energy, the result would be of very great importance in a variety of ways. Thus, if all the work obtainable from the tide filling and emptying great shallow basins, could be stored up, so that it might be given out steadily, and only at our pleasure; if all the work obtainable from wind-power, which is constantly varying, could likewise be stored up, so as to be readily available, a long-standing difficulty would be got rid of, which has hitherto prevented the working out of large schemes for the utilisation of these sources of natural power. And not only in these large cases, but in a countless number of other ways, is it important to possess means of storing energy. In the manufacture of gunpowder, and in many chemical operations, energy is stored up; but no such method can ever become economical. It has to be remembered, however, that electrical operations may be made as economical as we please; and however insignificant the method may appear to be just now, it may assume great importance in the future, from the fact that, with the exception of the lifting of heavy bodies to higher levels, an electrical method of storage may be made more economical than any other. Now when I charge this Leyden jar (experiment shown) you know that I store electrical energy, and I can use my stored energy at any future time if the insulation of my jar is good. Thus I have converted a small store into heat and light. (Experiment shown.) Again, I can use this store at any time to give itself out at a distant place. This is a very small store.

But now observe that my thermopile has been working for nearly an hour, and sometime ago it had filled these two test tubes with oxygen and hydrogen. With these two gases I can produce, as you all know, a most intense heat. You all know that this lime light is produced simply through my having such a store in these iron bottles which you see before you. Remember that these gases might be kept stored up for as long as we like, and that if a windmill worked a magneto-electric machine it could produce such a store working now fast, now slow. Well, but I can take this store and convert it again into electricity with very little loss. You will see that it can produce an electric current if we have two similar metal plates in the positions you see them in, and if I connect these metal plates through the galvanometer (experiment shown), you have there evidence of a current, this deflection of the needle of the galvanometer. This current will continue to flow, and the electric energy will continue to be given out until all the store of gas disappears.

Instead of using that weak thermopile, suppose I had used this strong current produced by the outside engine, you see how much more rapidly my store is formed. (Experiment shown, in which the gases rapidly formed were used to produce an oxy-hydrogen lime light.) I grant that the elaboration of this gas battery into a compact generator sufficiently powerful to produce very large effects, is a problem of some expense for future workers; but give it to any electrician, and make it worth his while, and I believe that such a generator might be constructed in a very short time.

To introduce the next part of my subject, let me ask—Can anybody hear the sound made by a puff of air as it passes through the hole in this cardboard disc? (Experiment made.) Nobody heard it, or the difference produced when the air was stopped by the cardboard. But suppose I repeat this operation several hundred times per second, you can all hear the powerful musical note given out. (Experiment.) You see, then, that the rapid recurrence of effects may be very sensible to us, although one such effect may not be sensible. In the same way, if light streamed through one of the holes in this brass disc into your eyes, it would not produce a very striking effect; whereas Professor Tyndall says that when such a disc as this was rotating so as to let the light falling on his eyes be very rapidly intermittent, he experienced the most extraordinary sensations. Again, if I very much alter the magnetic field in this telephone, by bringing a powerful magnet near it, with great care in listening I hear the faintest sigh, due to the diaphragm settling itself into a new position, its vibrations dying away as it does so; and if I brought a small magnet near, I should hear nothing. And yet the change of magnetism which produces the loud telephonic effects which we listen to is almost infinitely smaller. Why is this? It is due to the rapid recurrence of the effects. Now you are all aware of the importance of the telephone as a method of communication; I believe that a much greater importance is in store for it as a laboratory appliance.

Here is a selenium cell through which I can pass a current of electricity from this large battery, which also passes through these two telephones, which I can hold to my ears. When light falls on selenium its electric resistance is diminished,

and a stronger current passes. This is discovered by Mr. Willoughby Smit cannot hear in the telephone any effect by letting light suddenly fall on it. The difference of current produced in case before you is only one two-thousandth of a weber. But if I rotate this brass disc make the light fall with intermittent hundreds of times in a second on it I can distinctly hear a musical note is what Professor Bell has been exhibiting and it constitutes the principle of the phone. Now to give you an idea of the ground which the use of the principle is opening up in laboratory let me speak of an experiment which is in progress. Professor Bell spoke in his having tried to stop the intermittent light of this instrument by a sheet like this, but he found that there was a very faint sound from the telephone it occurred to Professor Ayrton that if ebonite is transparent to some invisible radiation, then in all probability capable of refracting such invisible radiation obtained this ebonite lens, and two tried. We thought the lens would focus invisible rays to a focus, but as our lens was mounted, so that we could move it itself, and as the rays are, of course, quiescent so that our eyes cannot help us to focus the lens, we did not succeed in this very experiment, which the following experiment ever, shows, must ultimately be successful. I placed the cell at A in this diagram (Fig. 2) that it gave out no sound, being beyond the beam of intermittent light. I placed the prism in the position B, in which it gave out our great satisfaction, a sound which we must remember that this sound, obtained from light that had passed through ebonite, was exceedingly feeble. I listened was in another room, so as to be in any way influenced by what he saw.

FIG. 2.

ciseness in detecting another experimenter pu

ad taking it away again. So that there is no doubt as to the origin of the faint sound. Well, the prism caused the light to bend, and now the question was as to how bending it produced. We procured pieces of zinc plate, with slits cut

You all understand, I hope, that advanced physicists regard a metal as an opaque body, even to invisible rays, so that only pass through the slit in our zinc. We placed the slit in the zinc within a short distance of the edge of the prism, and found a faint sound. The sound was faint. Then we searched on the selenium edge of our second piece of zinc, to find a slit of the cell might be covered without the sound. We found that region, and placed a second slit there. Rays passing through the first slit were now passing through the second slit. The sound changed in position, the sound died away. Thus, there could be no doubt that selenium refracted that invisible beam, but nothing else is as yet known. If our cell were very narrow we could have measured the index of refraction, but with the sounds were too faint to be heard at the centre of London; so all that we present is, that selenium certainly refracts light, and its index of refraction is, quite roughly, 1.7. Now, it is somewhat curious that this was the rough measurement made. For Clerk Maxwell's theory, that light is propagated through space like an electric disturbance, requires the square of the index of refraction, for light of very low frequency to be equal to the electric specific inductivity of the substance, and it has been known that this electric constant for selenium varies from 2.2 to 3.5 in different specimens; the square of 1.7 is 2.89. Thus, you see, our results following out of our first idea has rather backed up of Clerk Maxwell's electric theory of light. This and other matters which we are now proceeding to treat two important things, namely—first, the discovery of recurrent effects in the use of the selenium has opened up a new path into unexplored territory; and, secondly, the laboratory worker has been able to observe a hundred interesting phenomena, it to be investigated at once, and which will take up unless he gets more apparatus, eyes, and more observing eyes and working

ten years ago, it struck Professor Ayrton, when thinking how very faint musical notes he had heard distinctly from the telephone, in the noises in the neighbourhood, that an application of this principle of recurrent effects of far more practical importance than other, namely, in the use of musical notes as warnings in thick weather.\* You see that fog bells and horns are an old story, but that they have not been particularly

\*Reading of this paper, my attention has been drawn to the *Engineer*, of Jan. 26th, 1876, from Mr. H. T. who there suggests the use of submarine sirens as a means of warning in thick weather. Since the idea struck Mr. Ayrton and myself, we are glad to see how it has attracted so much attention. We now see that the authorities have made no effort in the way of carrying Mr. Humphrey's idea into effect.

successful, but our scheme was of a somewhat different kind. In northern Japan, where fogs are the rule and not the exception, which they are in England, and where changing currents of more than six knots are common off many dangerous parts of the coasts, ship-masters are very much in the habit of using their steam-whistles, listening for the echo from the steep coasts, and judging from the interval of elapsed time what is their distance from the coast, and what is their position. But they find that on many foggy days they can, and on other foggy days they cannot use this method, because they may hear no echo, although quite near the coast. Now, it seems to be forgotten by everybody that there is a medium of communication with a distant ship, namely the water, which is not at all influenced by changes in the weather. At some twenty or thirty feet below the surface there is an almost perfect calm, although there may be large waves at the surface. Suppose a large water-siren like this (experiment shown) is working at as great a depth as is available, off a dangerous coast, the sound it gives out is transmitted so as to be heard at exceedingly great distances by an ear pressed against a strip of wood or metal dipping into the water. If the strip is connected with a much larger wooden or metallic surface in the water the sound is heard much more distinctly. Now, the sides of a ship form a very large collecting surface, and at the distance of several miles from such a water siren as might be constructed, we feel quite sure that, above the noise of engines and flapping sails, above the far more troublesome noise of waves striking the ship's side, the musical note of the distant siren would be heard, giving warning of a dangerous neighbourhood. I have no time now to tell you of the small experiments we have made in this direction. This electric-bell sounds only very faintly when in water, and yet we have been able to hear it at the distance of sixty feet along a trough of water in a place filled with the noise of much heavy machinery. We took this water siren to Hastings for a trial in ordinary boats, but the weather was too rough at

FIG. 8.—SUBMARINE COAST WARNING.

An electro-magnet, with vibrating armature, giving out loud musical notes.

the time for boats to go out; and, therefore, the experiment had to be postponed. We have constructed the arrangement shown full size in this diagram, in which currents of electricity are sent from a distance sufficiently rapidly intermittent through this electro-magnet to give the natural period of vibration to this armature when in water (Fig. 8.) Whether this will prove successful or not we do not know, but we feel sure that the idea is to be carried out electrically, the source of sound being a motor worked by a generator on the nearest coast. In considering this problem, you must remember that Messrs. Colladon and Sturm heard distinctly the sound of a bell struck under water at the distance of nearly nine miles, the sound being communicated by the water of Lake Geneva.

Another application of the principle of recurrent effects, which may, indeed, be regarded as the earliest of such applications is this multiple telegraph of Mr. Elisha Gray, which my friend Mr. Graham has been kind enough to put in working order, so that it may be worked from this table to the telephones hanging against that wall. About this telegraph which allows a great number of messages to be sent through an ordinary telegraph wire at the same time, Sir William Thomson wrote to me in terms of high eulogium when he first examined it at Philadelphia. At present I believe that the quadruplex system is more favourably looked upon because it has succeeded better in practice, but I am inclined to think that in the distant future it may possibly have enormous development.

In this paper I wish I could bring in, as illustrations of the few great principles which are really the important factors in the future development of electrical appliances, the microphone and all the instruments which have been derived from it, but even to refer to them would take far too much time. I would end by speaking of two appliances which are of quite a different species, namely, Mr. Edward Bright's method of de-electrifying woollen yarn, and of a contrivance for seeing by electricity. In the manufacture, the woollen yarn becomes electrified by friction, and has hitherto lost its electricity very slowly, requiring to be stored for many months in damp cellars before it got rid of its electricity. Until lately, nobody seems to have suspected that it was electricity which caused the fibres to stick out on all sides of the yarn instead of staying in an interlaced condition. It was found to occur most in dry weather, and was vaguely put down by Englishmen to "the weather." So very annoying was this in a dry climate, that although Bradford men and Bradford machines were taken to America, only two months in the year could really be devoted to the manufacture. Now, we have here some wool-staple in the air which is being electrified by this plate machine. You see how the fibres repel one another and remain in this state. You observe, however, that these other fibres we try vainly to electrify because they are in a partial vacuum, and electricity escapes from them as rapidly as it is formed. I will allow air to enter this air-pump receiver, and now, when the machine is worked, you see—(Experiment shown)—that these fibres retain their electricity. The principle that a partial vacuum is very conductive has long been known to electricians, but the remarkable saving in woollen manufacture,

effected by applying a knowledge of the principle, was left for Mr. Bright. Mr. Bright's plan of operations is to have chambers of partial vacua may be produced. He wheels trucks of electrified bobbins of yarn into the chambers, and takes them out very soon, dried, thus performing, in a few minutes, a operation that used to be badly performed, in a manner, in half a year. Can we doubt that boys obtain, in all elementary school knowledge of electricity, there will additions to the number of electrical appliances.

And now let me come to the last of the developments of electrical appliances, still somewhat in the future. A picture of an aged couple at home seeing on the room wall an image of their children playing lawn-tennis out in India, and of their conversation with some of them by telephone, first led Ayrton and myself to think of this matter, and showed that it was feasible, in a letter to *The Times* and in the *Times* about a year ago. The principle of the method described by us was doubtless we therefore proved it at a meeting of the Physical Society four weeks ago. I mention it before you in a slightly different form. Suppose that place is York, and this is London. I have a little selenium cell at York on a part of this picture, and at London I can place at a corresponding place on this screen a square of light; and suppose that the illumination of the square is governed by a little movable needle which is attached to the needle of a galvanometer. Now when light falls on the selenium at York, an immediate change occurs in it, so more current flows to London, and this opens the shutter. The London square is then brightly illuminated. The York selenium is in bright illumination. If the York selenium is in shade or darkness, then the London square is in corresponding shade or darkness. (Experiment shown.) Now suppose that we form an image of this girl with a skipping rope at York, and cause a selenium cell at York to travel across her image, and suppose that this mirror at London moves so as to follow the illumination which passes the shutter to the London screen isochronously—an operation performed in several telegraph instruments. Whenever this cell reaches a dark, or a bright place in the image at York, there is a corresponding darkness, or shade, or brightness at the corresponding place in London. And now suppose the motion is effected rapidly enough, you are aware that if the shutter is only quick enough to answer its motions, the image of the girl on the screen at York traversed by the cell will be faithfully reproduced, and will remain on the retina at London as a distinct picture in black, grey, and white, just like a photograph. Then, perhaps, forty such cells as this all arranged in the way spoken of, or a smaller number arranged on a radial arm, it would actually be possible to show at London, not merely an image of a girl at York, but an image of a girl skipping. You may perhaps, understand better this principle from a model. Here is a path of black and white at York, over which this selenium cell is made to travel. We have continued the images to the screen above, simply to let you know when the cell is in the image of a dark place, and when it is in the

Fig. 9.

right place, so that you may be able to say there is a faithful reproduction at London. Two frames are really tied together by this string to make them move isochronously. In fact, I need hardly say that this function will be performed in another but quite as feasible a manner.

The cell at York is in a black part of the picture; it serves no light on that part of the screen in fact. The cell at York is in a bright part of the picture; the corresponding part of the screen at London is bright. And so we find that, as the frames successively through dark and bright so the corresponding parts of the screen at London are made dark and bright. (Experiment 1) Our shutter is not yet sufficiently dead-end for us to make this motion rapidly.\*

I hoped to be able to show you to-night the development of this method, by using what we called the Japanese-mirror principle. We showed that the most minute effects on the backs of metal mirrors, effects quite invisible when examining the polished surface of the mirror, are visible in the reflection of a divergent beam of light. Such effects, we believe, we can make by electro-magnets arranged radially round a circular mirror and rotating with it. A radial arrangement of magnets will move harmoniously with a radial arrangement of corresponding cells. The principle, however, is exactly the same as that shown by this model, only we know the change of curvature at a point in a mirror by changes of magnetic effects more rapidly than our shutter does.

I hoped to be able to present to you the model which Mr. Shelford Bidwell has proved to be capable of reproducing in shaded lines on glass by electro-chemical decomposition, a picture of an instant stationary object. I understand, however, that Mr. Bidwell has been asked to make a paper here, when he will exhibit the model made.

My paper read here a year ago it was the impression of giving artisans facilities for obtaining a more exactly exact knowledge in science that I have laid stress on. To-night I have desired to show what benefits our country would

receive from an exact knowledge of electrical magnitudes, and of the fundamental laws of electricity being more widely disseminated, and, second, how the principle of recurrent effects may be employed to assist our senses.

#### DISCUSSION.

The Chairman said, in the usual course of things he should have liked to invite discussion on some of the many points referred to in this most interesting paper, but it was now so late, that although it would be permissible for any one to make an inquiry, it would be impossible to have a full discussion. He, himself, should like to ask a question on one point, which was this—Did he rightly understand Professor Perry that the whole power of the Falls of Niagara might, under some circumstances, be transmitted to New York through a single telegraph wire? It appeared to him that the enormous difference of potential at the two ends of the wire, and the large quantity of electricity passing, would cause more than sufficient heat to fuse the wire.

Professor Perry said his notion was what had been stated, and that he believed was the logical mathematical deduction from the fundamental laws of electricity; and in this Professor Ayrton agreed with him. It was the current of electricity passing through the wire which produced the heat, and if only a very small quantity passed through it could not be fused. Now the quantity of electricity was only one factor, the energy transmitted was equal to the potential  $\times$  quantity. Suppose the one were 1,000,000, and the other 1,000,000  $\times$  1 = 1,000,000; if the one became  $\frac{1}{2}$  and the other 2,000,000, the product was equally 1,000,000; and if one factor became  $\frac{1}{1000}$ , and the other 1,000,000,000,000, the result was still 1,000,000; the product was always the same, and the smaller factor might be made as small as you pleased. That was their contention, and though it was very probable they might never be able to produce practically the perfect insulation required, he believed the theoretical deduction was sound.

Professor Ayrton said the lecturer referred to the difference of potential, not at the two ends of the wire which transmitted the power, because, of course, where there was much difference of potential at the two ends of the wire, there would be a tolerably large current passing, but the difference of potential between the wire at each end and the earth. The difference of potential between the two ends of the wire would be exceedingly small, and, therefore, the current flowing through would be exceedingly small; but the difference of potential between any parts of the wire and the earth would be extremely large, so that much work could be

\* On the reading of the paper, it was found that even with the shutter it was nearly possible to make the motion fast enough for the eye to see by the retina of a complete image of the path traversed. Proceedings of Royal Society, No. 191, p. 127, 1878.

put in at the generating place, viz., Niagara, and much work would come out at the motor place, viz., New York, but the current flowing through the wire, which depended upon the difference of potential between the two ends, would be exceedingly small, because, though each would be very high, they would be nearly equal to one another. Consequently the waste of energy in electric friction would be small.

The Chairman said he thought this explanation had thrown considerable light on the point referred to, which was one of great practical importance. He begged to move a hearty vote of thanks to Professor Perry for his very interesting and instructive lecture, and for the experiments which had accompanied it.

The vote of thanks was carried unanimously, and the proceedings terminated.

## MISCELLANEOUS.

### FIRES IN THEATRES.

The following remarks on the necessary arrangements for public protection from fires and panics at theatres and other public establishments, are taken from the report of Sir Edwin Chadwick, C.B., to the Committee on the Prevention of Fires and on the Public Protection, dated July, 1877,

speciality of service applicable to the particular case. The highest architectural practice. The fire necessarily accompanies the elaborate and costly edifices for warm and ventilation. The application of such means, to the Houses of Parliament, by the late Dr. Reed, Sir Goldsworthy Dr. Percy. In Paris it was led by M. de la Motte, and now by General Vour le Blanc, and Mons. Charles Joly. The new Grand Opera at Vienna are becoming elaborations of no mean order, and between five and six miles of pipe to be regulated for its lighting, to be regulated for its lighting, cation from a central office to conditions of all parts of the theatre. The provisions against fire, in it, were correspondingly elaborate, in the larger co of science, in the larger co in their degree to lesser buildings should be submitted, be made them in connection with the general police service, with such consultative scientific the Houses of Parliament executive service of public protection."

### PRESS

Mr. C. Shaler Smith to the American Society of many years

In the middle tornado, he had yet to find a storm swath in the path of the vortex, wherein the force exceeded 50 lbs. per square foot, was more than 60 feet wide. This storm swath is a cam in point. This whirlwind swath about 1,000 feet wide for fourteen miles destroyed over three hundred houses, and a loss of over 84 lbs. per square foot at its maximum effort. It crossed the middle span of the Ohio bridge nearly at right angles, and a pressure of 52½ lbs. per square foot in the center crushing a barrel of tar, which stood on the path of the vortex. The width of the swath was marked on the span by the circle of the tar was spun around, the wreckage left the points at which it ceased to destroy the bridge. The width was then shown to be slightly over 60 feet. Guided by this, Mr. Smith was subsequently able to locate the path travelled by the central vortex throughout the entire length of the storm swath. The swath was uninjured, although it was only able to withstand 30 lbs. per square foot, and a strain of 20,000 lbs. per square inch on this span was 320 feet long, 30 feet deep, and the top chord was 120 feet above the water. He considers it very unlikely that a swath of over 200 feet span will ever be exposed to a pressure of more than 30 lbs. per square foot, acting in one direction over its entire length. Next, a passenger train and the heaviest possible freight train will leave the track at the respective rates of 31½ and 56½ lbs. per square foot. If the track is proportioned at 15,000 lbs. per square inch, and a pressure of 30 lbs. per square foot, they will be within their limit of elasticity at the time when the train is blown from the track in either direction. The effect of derailment, to resist which strength in the wind bracing will be of no avail, if there is no tension in the pier columns. When wind pressure is reached, and these are properly spliced and anchored, as per specification, there will be an ample margin of tensile strength in any case where this pressure may be expected. Last, in view of the comparative rarity of severe strains and the consequent slight fatigue of the iron is exposed, the high stresses imposed and bracing are perfectly legitimate.

### THE WAX PALM IN PERNAMBUCO.

The wax palm (*Copernicia elæfera*) seems to be more important plant in some parts of Brazil generally supposed. In Pernambuco the plant is abundant, and the uses to which it is put are numerous. The wood, for instance, is used as both as beams or rafters, and as laths upon which to support the tiles; the fruits are used for feeding, and the leaves are used for making hats and a valuable medicine is obtained from the roots, as recently been brought to notice in this country. From the shoots or leaves a wax is obtained. Suppose they are cut before they unfold, dried in the sun, powdered and boiled, the wax rising to the surface of the water. This wax, it is stated, is not procured in any quantity that it might be worth, in a recent report of her Majesty's Consul at Pernambuco, that the export of this wax during the year 1878 amounted to 18,668 kilos., valued at £758; in 1879, 171,000 kilos., valued at £8,967; in 1877-78 80,483 kilos., of the value of £3,168; and in 1876, 1,543 kilos., valued at only £61. By far the most common use of this wax finds its way to this country. It is that the decrease during the last year was due to famine and drought which so severely crippled the wax trade in the province. It is not a little remark-

able that, at a time when roasted date stones are proposed as a substitute for coffee, we should also learn that the stones or seeds of the Camanba palm, when roasted, are used in Pernambuco as coffee.

### THE NEW EDDYSTONE LIGHTHOUSE.

The following particulars respecting the progress of the works at the new Eddystone Lighthouse are given by the Architect —

"The masonry up to the fifty-second course, which is 30 feet above low-water mark, has been completed. It is now on a level with the light of the old tower, thus the new tower already intercepts the light from the old tower over a very perceptible area, viz., 12 degrees near the reef. This would soon be passed over by a ship, but at five miles distance there would be a mile of darkness on a true south-west course. It was intended in the original specifications to provide for this interception by placing a second light in the new tower at the same level as that in the old tower, so screened as to be visible only within the limit of the dark arc. There was also to have been a temporary bridge from one tower to the other, so that the second staff of light-keepers might have communication between the two towers. This, however, is not to be carried out, and the Trinity Corporation have given public notice to mariners that there is such a dark arc, and the cause of it. The fifty-first course, which was laid a few days ago, is a floor course, and completes the fourth apartment above the well. The room just completed is the crane-room, and is provided with two doors besides a window, one facing south and the other north, so that stores may be taken in from either one side or the other, according to the state of the weather. The three rooms below this will be occupied as oil and general store rooms. The room immediately above the crane-room was to have been occupied by the white fixed subsidiary light, which is to cover the reef of rocks known as the Hand Deep. The rocks bear from the Eddystone Lighthouse three and a quarter miles in a direct line between it and Looe Island. At low water there is a depth of four fathoms of water upon them. Although this would be ample for ordinary craft in fair weather, yet in rough weather it may go ill with even a small vessel in the trough of a sea, much less one of a larger class, or, perchance, an ironclad. This subsidiary light will only be seen within the area above named, and when in the vicinity of danger. It is now intended that this subsidiary light shall be placed a room higher, so changing places with the living rooms. These modifications, together with the preparation of the light itself, are being carried on in the yard at Orston, and afford occupation for the men when they are not able to work at the rock. In external appearance the new tower will be a complete alteration from the old both as to height and colour, being nearly as double as high, and of uniform granite, like the breakwater lighthouse. The light itself is to be a modification of the plan recommended by Sir William Thomson. Instead of a fixed white light, as at present, it will be oscillating. The light will be a powerful white double-flashing half-minute light, showing two successive flashes of about 2½ seconds' duration, divided by an eclipse of about four seconds, the second flash being followed by an eclipse of about 21 seconds. The light will be visible all round the horizon, but from its more elevated position it will be seen in clear weather 17½ miles, and its field of visibility will overlap that of the Lizard, instead of there being, as now, eight miles of darkness. Out of the 2,200 stones, of which the tower will consist, over 1,500 are already in position. At the present rate of progress, therefore, it is probable that next autumn's excursionists will witness the completion

of the tower, and mariners are informed by public notice that the new tower will be ready for the exhibition of a light early next March."

### COCA (ERYTHROXYLON COCA).

In Mr. Markham's "Peruvian Barks," recently published, he has given the results of his own observations, and collated that of other travellers, respecting this substance, and to this account we are chiefly indebted for the following facts:—

"Coca," the "beloved narcotic of the Peruvian Indian," was first named botanically through the labours of Joseph de Jussieu. The history of this noted botanist is a melancholy one. He left France in 1735, in the ever memorable expedition of La Condamine, and after M. La Condamine left South America, M. Jussieu continued his botanical researches, making numerous journeys on foot, notably those to the Cinchona regions. The results of fifteen years labours were contained in certain cases of dried plants, &c., and a native servant at Buenos Ayres, thinking these cases contained money, stole them, and this loss had such an effect on poor Jussieu that he returned to France in 1771 deprived of reason.

The coca is the great source of comfort and enjoyment to the Peruvian Indian. It is to him what the kava-kava is to the South Sea Islander, the betel to the Hindu and Malay, and tobacco to the rest of mankind, but with this difference it produces invigorating effects. The Peruvian Indian looks upon coca with veneration. In the palmy days of the Uncas or Yncas, coca was sacrificed to the sun, the high priest or Huillac Umu chewed it during the ceremony, and before the arrival of the Spaniards, coca was used in lieu of money. After the Spanish Conquest, much was done to prescribe its use, because as a Council of Bishops held in 1569, said it was a "useless and pernicious leaf, and on account of the belief stated to be entertained by the Indians, that the habit of chewing coca gave them strength, which is an illusion of the devil." Coca, indeed, from its popularity, being used by about eight millions of people, has always had a great commercial importance, and one Viceroy, Don Francisco Toledo, issued no less than seventy ordinances concerning coca in the space of four years (1570-1574).

The coca plant is a shrub of four to six feet high, with straight and alternate branches and leaves like those of the tea plant, and is cultivated at elevations of from 5,000 to 6,000 feet above the level of the sea in the warm valleys of the eastern slopes of the Andes. Here the only alternations of climate is from wet to dry, frost is unknown, and it rains more or less every month of the year. The seeds are sown on the surface of the soil as soon as the rainy season commences, and begin to sprout in a fortnight, being carefully watered, and protected from the sun by a thatched roof. The following year the seedlings are transplanted in a soil carefully broken up and freed from weeds. The ancient custom was to raise the plants in terraces on the hill sides, but now plantations on the level ground are resorted to, although Indians aver that plants raised under the former conditions yield a much superior quality of leaf. At the end of 18 months the first harvest is ready, and the picking of the leaves, performed by women and children, is very carefully proceeded with, so as not to injure the young and still tender shoots. As soon as one crop of leaves is removed, if well watered, and the ground carefully weeded, another crop is ready in about 40 days. A plant continues to yield for about 40 years and Dr. Poeppig gives the profit of a coca plantation as about 45 per cent. Each picker carries a piece of cloth in which the leaves, plucked one by one,

are placed. These leaves are then taken to a drying yard, formed of slate flags. Here they are spread out in thin layers, and carefully turned in the sun. Too much exposure to the sun spoils the flavour of the leaf, and if heaped too much the leaves ferment and become fœtid. As soon as dried, the leaves are packed in bags made of llama leaves, with an outside covering of cloth, and sent in larger parcels of about 50 lbs. each.

In the Sandia district of Carabaya, two varieties of coca are recognised, the Ypara and the Hatun coca, the latter having a larger leaf than the former.

In Bolivia, coca is treated as a Government monopoly, and the right is generally farmed out. In the Yungas brought into that country's exchequer a sum of 100,000 dollars. The whole yield of coca in South America is estimated at thirty millions of pounds. Coca deteriorates in keeping, and Indians treat it as a loss if kept longer than seven months.

Such is the faith in coca, that it is believed that a man can but taste a coca leaf when placed on his tongue, and his future bliss is assured. No Indian is without his coca bag made of llama cloth, and at the end of a day, sitting down, he takes leaf by leaf and puts it up in his mouth till he forms a ball. Then he takes a small quantity of powder consisting of camellia oil, made by burning the stalks of the quinoa mixed with lime and water, he goes on his way. The use of coca is widely spread. The high cold slopes of the Andes has but the little maize as his sole nourishment, and the messenger looks to it as his solace and food. As to the properties of coca, it seems very probable that it allows of a greater amount of fatigue and lesser amount of nourishment, and prevents the respiration in ascending steep mountains. It has an agreeable and aromatic taste, accomplishes slight irritation, which excites the flow of saliva. When made into a tea, in taste it is like the tea, and effectually prevents drowsiness. Externally as a poultice, it moderates rheuma brought on by exposure to cold and wet, and headache.

Mr. Markham chewed coca leaf very frequently, and states that he found it to produce an agreeable feeling, that he could endure longer abstinence from food with less inconvenience, and that when he could ascend precipitous mountain sides with a lightness and elasticity, and without losing breath, he also considers it the least injurious of all other stimulants, even when taken in excess, and at the same time the most soothing and invigorating.

### NOTES ON BOOKS.

**An Agricultural Class-Book for the use of South India.** By William R. Robertson. 1880.

The author, who is the Superintendent of Government Farms in the Presidency of Madras, has here published a book which is intended not only to enable school children to qualify themselves for the Agricultural portion of the Upper Primary and Middle School examinations, but also to give information to those engaged in agricultural pursuits. The subjects dealt with are the preparation of land for cultivation, tillage, sowing, and tillage operations, manures, irrigation, farm crops, and farm stock. The author points out much of the suffering in South India from famine is due to bad farming, and what need there is of superseding the tillage implements now in use by improved labour-saving tools.

ing; a Text-book to the Practice of the Art of the Plumber, with supplementary chapters House Drainage, embodying the latest improvements. By William Paton Buchanan. Second edition. London: Crosby Lockwood and Co., 1880.

First edition of this little book was published in 1874, the object of affording a handy text-book for the domestic plumber, but the present one has been revised somewhat, in order to make it useful to a wider circle of readers.

The volume is divided into thirty-one chapters, treating of different subjects connected with the plumber's trade. The roof, with its gables and ridges, is first dealt with, then comes the arrangement of the pipes, the drains, the baths, and the cisterns; the more important questions of water supply are then treated, and the book is completed with remarks on disinfectants, and general drainage. The author points out how important it is that the occupant of a house should understand the ramifications of pipes, which, if badly laid, may expose him to such baneful influences. The present is the era and grand opportunity of plumbing, and in order to bring it to perfection the architect and the plumber must work in conjunction, and together do whatever in them lies to such a result as will be both creditable to them, and a blessing to the community at large."

## GENERAL NOTES.

Meeting of Naval Architects.—The meetings of the Institution were held in the Rooms of the Society of Arts, on Monday, 6th inst., Thursday, 7th inst., and Friday, 8th inst.

A Light in Coal Mines.—The Swan electric light was used for the first time at the Cannon-street Station, to be "laid on" to Mr. John Hearnock Colliery, Motherwell, and will extend to stations, the roadway, the station where the underground engine is placed, and possibly the miners' working places.

Light at the Cannon-street Station.—The light was used for the first time at the Cannon-street Station on the evening of the 31st ult. The arrangements for the lighting of the station and the Brockie arc lamps, which have been carried out by the British Electric Company. Eight powerful lights of 8,000 candles each were suspended from the roof of the station at a height of 100 feet from the platforms, and there are two lights at the station. There are two circuits for the ten lights, each, and the current for each circuit is produced by the large new type of Gramme machines recently ordered by the British Electric Light Company, which number of arc lights in series.

Compressed-air Clocks.—A Bill is now before Parliament giving London the benefit of the system of compressed-air clocks, which has been extensively established in Paris. Compressed-air clocks consist of a new and simple construction of the works of the ordinary timepiece, by which all parts of the works of the ordinary timepiece, by which all parts of any city or town, however much separated and from each other, can be governed and wound up and set by means of a pneumatic air current and connection, which secures their regular going and their synchronization. The movement can be applied to any clock or timepiece, wherever placed, and there is neither one central motor or several, according to the size of the municipality. If the system were adopted in London, as proposed by the Bill already introduced, which has the consent and sanction of the City and the Metropolitan Board of Works, the result would be that every clock embraced within the system, no matter where situated, would always indicate precisely the time of the day or night. The number of stations proposed for the metropolis by the promoters of the Bill now introduced is ten. The maximum charge for public use is not to exceed 12s. 6d. per annum.

Plant Labels.—Mr. W. Ingram, the gardener of the Duke of Rutland, writes to the *Gardener's Chronicle* on this subject:—"I hope the very liberal prize offered by Mr. Wilson for a good plant label will stimulate the inventive faculties of gardeners and others, and that we shall at length secure something on which to register the names of plants prominently and distinctly, and thus be saved from the annoyance of obliterated names that has too often followed from the use of the old easily made and quickly perishing label of wood. As our plant collections increase—and they are increasing rapidly—we feel the want of a fresh label more and more, and I trust that Mr. Wilson's example will be followed by others, and a second and third prize offered for meritorious inventions in plant labels. I have tried many kinds, and have suffered the disappointment that has doubtless attended the efforts of the donor of the prize in his search for a permanent and readily-made label. Wood, paint, and pencil must be abjured for all but temporary purposes. Zinc and indelible ink, which seemed to offer some advantages, have disappointed me. Terra-cotta has crumbled under the power of frost and wet; even iron corrodes, and, good as it is for some purposes, cannot readily be made use of. We want the medium that offers the facilities given by wood, paint, and pencil, and yet gives the durability of a record inscribed on iron—something that can be quickly fashioned and inscribed, and when done will remain impervious to the action of weather—that will bear rough treatment—that a foot cannot crush, nor the wind nor frost remove, and, with all this, is not obtrusively large—no more conspicuous than the plant it names. Then we want distinctive labels for the various cultivated plants, small and neat for pot plants, strong for shrubs and herbaceous plants, plain and easily read, and readily affixed for fruit trees; and one prize will scarcely include all these. Surely the authorities of botanical gardens might co-operate with Mr. G. F. Wilson in his laudable endeavour to secure a good plant label."

Seaweed Jelly.—The seaweed, *Arachnoidiscus japonicus*, which is used by the Japanese and Chinese to pack porcelain and other articles for exportation, is said, by the *Journal of Applied Science*, to be made use of in France for the purpose of making a spurious fruit jelly. When placed in a tumbler of water, it absorbs the water in a few minutes; then a number of shoots grow, and constitute a jelly nearly as transparent as the water from which it is made. The jelly is easily sweetened with glucose, and cochineal or other colouring matter is added with equal facility to imitate the colour of the fruit. The perfume and the taste were the only real difficulties that remained to be overcome. After considerable study, it was discovered that, by using a mixture of certain ethers with tartaric acid, glycerine, &c., a perfect imitation of the odour of raspberries was produced. By putting a little of this essence to the seaweed which has been allowed to develop itself in water, a substance is obtained which has the consistency of fruit jelly, though no fruit has been used, which is sweet, though no sugar has been employed, and which has the colour and fragrance of raspberries, though altogether destitute of that fruit. When this essence is placed, another very good fruit flavour is produced by treating castor oil with nitric acid. The jelly still retains a little of the fibrous nature of the plant, and has a tendency to split and fall to pieces, instead of forming adhesive lumps. Examined by the microscope, it has no resemblance to the jelly made from fruit. Then, as the jelly must be coloured, it is easy enough to discover the presence of an artificial dye. Without resorting to the laboratory, it suffices to dissolve a little of the suspected jelly in some tepid water, and dip a white silk ribbon in the solution. If it is a natural jelly, the ribbon will only be a little soiled; but if the jelly has been artificially coloured, the ribbon will also be coloured.

Purifying and Bleaching Sponges.—M. Blondon gives the following receipt.—The sponges are first washed in tepid water, and then in a solution of hydrochloric acid (5 cubic centimetres = 0.5 cubic inches, to 1 litre = 1.1 pint), which frees the pores from carbonate of lime. To bleach them, they are immersed, for 24 hours, in a solution composed of five parts of hydrochloric acid to 100 of water, with the addition of six parts of hyposulphate of soda. In this way sponges may be bleached much more effectually and rapidly than with sulphurous acid.

New Application of the Sub-products of Coal-tar.—Mr. Sanders, of St. Petersburg, has succeeded in producing from the heavy oils of coal-tar, a new substance which, in

many cases, takes the place of india-rubber with advantage. It is prepared in the following manner. A given weight of a mixture in equal parts of wood oil and coal-tar oil, or of coal-tar and hemp oil, is heated for several hours, at a temperature of about 318° Fahr., so as to disengage the injurious substances and increase the viscosity of the mass, until it may be drawn out in threads. A second quantity, equal to the former, of linseed oil, preferably thickened by boiling, is now added, and also from one-twentieth to one-tenth per cent. of ozokerit with a little spermaceti. In the meanwhile, the mass is kept at a uniformly high temperature for some hours, when from one-fifth to one-half part of sulphur per cent. is added, after which the product is moulded or otherwise worked in the same manner as india-rubber. The proportions of the three oils named above may be varied so as to obtain a harder or a more elastic substance, as may be required. The product is elastic and tenacious, standing the weather better than india-rubber, and is not deteriorated by great pressure or a high temperature. It is said to be specially suitable for the insulation of telegraph wires, and may be employed alone or mixed with india-rubber or similar resinous substances.

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

APRIL 27.—“Five Years' Experience of the Working of the Trade Marks' Registration Acts.” By EDMUND JOHNSON.

MAY 4.—“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MAY 11.—“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works). WILLIAM SPOTTISWOODE, LL.D., P.R.S., will preside.

MAY 18.—“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS. Dr. SIEMENS, F.R.S., will preside.

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock

APRIL 28.—“Impurities in Water, and their influence upon its Domestic Utility.” By G. STILLINGFLEET JOHNSON, F.C.S. ALLEN THOMSON, M.D., F.R.S., will preside.

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Prof. A. K. HUNTINGTON.

MAY 26.—“Telegraphic Photography.” By SHEPHERD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

### INDIAN SECTION.

Friday evenings, at eight o'clock:—

APRIL 29.—“The Building Arts of India.” By General MACLAGAN. ANDREW CASSELL, Member of the Indian Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PRATY, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Four Lectures.

### Syllabus of the Course.

#### LECTURE III.—MAY 2.

Fringes. Twisted thread-work in the 15th century. Early designs for plaited threads. Italian, Flemish, French, and Irish lace. Laces of primitive design.

#### LECTURE IV.—MAY 9.

Resumé as to styles of design in hand-knitted lace. Traditional patterns. Sketch of the inventions for knitting and weaving threads. Differences between machine and hand-lace. Modern hand-made laces at Buxton, Honiton, &c.

This course will be illustrated by special diagrams and photographs enlarged with means of the lantern and oxyhydrogen light.

The Fifth Course will be on “Colours and its Influence upon Various Industries.” By R. BRUDENELL CARTER, F.R.C.S. The

May 16, 23, 30.

### MEETINGS FOR THE ENSUING

MONDAY, APRIL 18TH... Asiatic, 22, Albemarle-st.

TUESDAY, APRIL 19TH... Pathological, 53, Berners-street, W., 8½ p.m.

WEDNESDAY, APRIL 20TH... Institute of Bankers (the London Institution, Finsbury-circ.) Mr. John Smith, “The Government Meteorological, 25, Great George-street, Dr. Wladimir Köppen, “The Frequency of Rain.” 2. Mr. G. M. Whipple, “Instruments made at the Kew Observatory.” 3. Mr. G. M. George’s Barometers.” 3. Mr. G. M. Discussion of Mr. Eaton’s Table of Height at London, with regard to Per Archaeological Association, 32, Sackville-st., 8 p.m. Mr. H. Syer Cuming, “Seal Templars.”

THURSDAY, APRIL 21ST... Mechanical Engineers, 4, street, S.W., 7½ p.m. Reading and discussing papers:—1. M. Le Baron Clauzel, “Special Reference to Ship-work.” 2. Kennedy, “Results of Experiments on made for the Institution of Mechanical Engineers.” 3. Mr. W. W. Beaumont, “Thrashing.” 4. Mr. J. J. Tylor, “Meters for Regulating Water.” 5. Mr. A. A. Langley, “On Dredging.”

Linnean, Burlington-house, W., 8 p.m. Balfour, “New Genera of Plants from Mr. Edgar A. Smith, “The Fresh Australia.” 3. Mr. B. Daydon Jackson, “*Hibiscus palustris* (Linn.) and certain other species.” 4. Dr. W. A. Herdman, “Individual Branchial Sac of Simple Ascidians.” Chemical, Burlington-house, W., 8 p.m. Brown, “Fractional Distillation.” (1) W. E. Adeney, “The Estimation of Potassium by Means of Potassic Permanganate.” Dixon, “The Oxidation of Sulphurous Acid.” Royal Historical, 22, Albemarle-st., W. Frederick G. Fleay, “History of the from their first opening in 1576 to the present.” 2. Mr. J. Baker Green, “The Analogies and Christian Baptism in the Apostolic Church.” Numismatic, 4, St. Martin’s-place, W. Civil and Mechanical Engineers, 7, Western-st., S.W., 7 p.m. Mr. J. H. Maughan, “The Lincolnshire.”

FRIDAY, APRIL 22ND... Mechanical Engineers, 4, street, S.W., 7½ p.m. Reading of papers continued.

Quekett Microscopical Club, University, 8 p.m. Mr. T. Charters White (F.R.S.), “Histology of the Gustatory Organs of the Tongue.”

Folk-Lore, 22, Albemarle-street, W., 8 p.m. Clarke, “The Relation of English Literature to the English Language, and the Influence of the French.”

Clinical, 53, Berners-street, W., 8½ p.m. SATURDAY, APRIL 23RD... Antiquaries, Burlington-st., 11 a.m. Annual Meeting. Royal Botanic, Inner-circle, Regent’s-park, 10 a.m.

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,483. Vol. XXIX.

FRIDAY, APRIL 22, 1881.

Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## PROCEEDINGS OF THE SOCIETY.

## FOREIGN AND COLONIAL SECTION.

April 5, 1881; JOHN RAE, M.D., F.R.S.,  
Chairman.

Business read was—

## THE OLD COLONY AND THE NEW DOMINION.

By E. Hepple Hall, F.R.S., &c.

## I.—HISTORICAL.

Every estimate may be placed upon the Canada as a field for British settlement, in comparison with those offered by other portions of the British Empire, there can be no question of the amount of interest which our Home Colony presents from a historical point of view. Her history is indeed as unique as it is recent.

No part of our world-wide colonial empire has passed through so many or such ages of existence. Nowhere within the limits of the Crown territory have peace and war, union and separation, loyalty and rebellion, followed one another in such quick succession. In the struggles between Church and State, between party and party, between Parliament and the people, there have been more bitter, or the great political changes which they have contributed to hasten have been more sudden or more sweeping. Nowhere has the patriotism of the subject, the supremacy of the flag, or the prestige of our flag been more dearly prized, and nowhere have they been more heroically sustained than in Canada. It will be my honour and privilege, as a member of the Society, to speak of which I have now to submit, to the varied stages in her history; to note her progress from the infant quasi-colony of a foreign power to the proud position which she now occupies as an integral portion of this great empire; to show how, as well as the short time allowed me, the more important political changes in each succeeding stage has been marked, and how, as far as practicable, the results of the present current of events is likely to be.

From the beginning, there was little doubt of the early existence of Canada to indicate the position which she has already acquired;

still less was there to foreshadow the greatness to which she is surely yet destined to attain. The hardy and adventurous Norsemen, if they ever really sighted the Canadian shores, which is extremely doubtful, certainly never landed on them. The occupation at least, if not the discovery of the country, was reserved for later times, and for another race of people. The best authenticated discovery and earliest attested history we have of the country now called Canada are associated with the exploits of that brave band of Venetian navigators who shed such lustre on the closing annals of the fifteenth century. Our North American and South African colonies started in the race of empire—rather let us say took up their appointed places in the circling orbit of our civilisation—together.

While Diaz and Vasco de Gama were seeking a new route to India by way of the Cape of Good Hope, the Cabots, father and son, were tracking the stormy Atlantic, and hunting for a north-west passage, in hopes of ultimately reaching the same goal.

In the very same year (1497) in which the Portuguese navigator weathered the Cape of Storms, and sighted the low-lying coast of Natal, his Italian compeer, accompanied by his son Sebastian, leaving their adopted home, Bristol, in the little barque *Mathew*, which the English monarch had given him, caught the first faint glimpse of the iron-bound coast of Newfoundland. It was only a glimpse, a first sight, a *prima vista*, and so Cabot called it. Two years subsequently to Cabot's voyage, Gaspar de Cortereal, a Portuguese adventurer, hoping to accomplish what his predecessor and competitor had failed to find—a north-west passage to India—set sail from Lisbon, and with two ships reached the Labrador coast, which he named "Terra Verde." He entered the Gulf of St. Lawrence; but of further exploration by him we have no authentic trace.

Thus far discovery on the North American coast had resulted wholly from the desire to discover a north-west passage to India. Not only was the island which now bears the name Newfoundland an actual *terra nova*, but the Labrador coast, and Acadia to the south of it, were in the same category of newly discovered or found lands; and thus they stand roughly outlined on the maps of that period.

*Period of Settlement.*—The first voyage to North America with a view to settlement is that recorded by Mr. Beamish Murdoch, of Baron Lery et de St. Just, in 1518. Six years later, Francis I., of France, aspired to enter the lists with Spain and Portugal for the acquisition of territory and sovereignty in America. Under his direction, Giovanni Verrazano, a Florentine, was despatched (January 17th, 1524) in the ship *Dauphine*, with fifty men, and provisions for eight months. Little came of Verrazano's visit, save the glory of the occasion. Similarly barren of practical result seems to have been the visit of a "learned and wealthy English citizen of Bristol," Master Thomas Thorne by name, who, favoured with the patronage of King Henry VIII., fitted out two ships, and set sail in May, 1527. Entering the Straits of Belle Isle, and through them reaching the Cape Breton and Acadian shores, the ambition of Thorne and his companions, or more likely their provisions,

failed them, and they returned to Bristol in October of the same year.

Thus fitfully and feebly were the attempts to found settlements on the coast of North America carried on, until the close of the first quarter of the sixteenth century. England's flag of discovery had been thus far wholly in the hands of foreigners; and he would have been a bold man who would then have predicted that England would so soon become the first maritime nation in the world. A floating population, consisting of a few hundred hardy, but humble, Norman and Breton fishermen, roughly subsisting on their frail barques and brigs, anchored on the open Newfoundland banks for seven months in the year, scudding before a stiff nor'-wester, or sheltered between the headlands on some part of the Acadian coast, formed the only appearance of what could be called a settlement or colony. It is not until we come to the French exploration and occupation, that we reach what may fairly and distinctively be called the first period in the history of Canada. This period opened with the voyage and landing of Jaques Cartier, in 1534.

*French Occupation.*—During Cartier's first visit little was accomplished in the way of actual settlement. Capture and conquest, or conversion, not colonisation, have ever marked the policy of the French in the New World. Cartier seems to have contented himself with anchoring his little fleet off the ancient Stadacona, at the confluence of the St. Charles and St. Lawrence rivers, and of afterwards navigating the river as far as Hochelaga, where he made the acquaintance of the Huron-Iroquois tribe of Indians, and of their king or *Agouhanna*. Cartier's next visit was made in 1541, in company with Francis de la Roche, Sieur de Roberval, whom the French monarch had created Lieutenant-General and Viceroy of his newly-acquired possessions. This was intended as a colonising expedition, the first of any magnitude of which we have any record. But, like that undertaken by Baron Lery in 1518, and, indeed, like most French colonising schemes, it was a failure.

The first actual settlement by Europeans within the territory of the present Dominion of Canada was made in 1605, by De Monts, at Port Royal, now Annapolis, in the province of Nova Scotia. This followed immediately on the formation of the "Company of New France," under patent from Henry IV., for "inhabiting Acadia, Canada, and other places in New France." Events now followed more rapidly. On July 3, 1608, Samuel de Champlain reached the bold headland at the confluence of the St. Lawrence and the St. Charles rivers, the spot where his brave countryman, Cartier, had wintered three-quarters of a century before, and founded the City of Quebec, and where fifteen years later he built Fort St. Louis. From this time till 1629, French exploration and colonisation in Canada was carried on mainly, if not wholly, by the priests. Bands of missionaries penetrated the country in all directions, zealously endeavouring to convert the Indians to the Christian faith. From Quebec, as a starting point, the missionary lines of the "Society of Jesus" radiated in all directions through every inhabited region, from the Laurentian Valley to the Hudson's Bay territory, through the region of the great lakes, and down the valley of the Mississippi. Scantily equipped, with a

breviary round the neck and a crucifix the fearless priest set forth, the commerce, and the *avant-courier* of Christianity and commerce went hand in hand through Canada in 1630—1670, just as Central Africa to-day, the merchant by the missionary. Conspicuous among M. Joliet and Pères Hennepin, Marquet and Dablon. Lasalle, setting forth Frontenac, had pursued his way to the extremity of Lake Michigan, the side of Dearborn and of Chicago in later days reached October 18, 1678. Four years later the same intrepid adventurer took possession of the Mississippi Valley in the name of the French king and claimed it as part of New France.

In 1670, Charles II. granted to Priu and his company of adventurers, since the Hudson's Bay Company, rights and which have worked a mighty revolutionary change in the future of the whole North-West.

*Consolidation of British Power.*—Although actual and sovereign dominion of Canada ceased with the famous passage on the heights of Abraham in 1759, and the defeat of Montcalm, and the capture of Montreal in 1760, French influence could be felt in various ways. After the capture of Quebec, the country was placed under British rule. The French Canadians were guaranteed free exercise of their religion, and they continued to enjoy their accustomed privileges. "La Nation Canadienne," though politically, was yet socially and ecclesiastically vigorous and active as ever. The difference between England, France, and Spain, which left England constitutionally stronger, was only a prelude to further disturbance. In 1775, the Quebec Act was passed, which contained in this Act is to be found the seeds of that anti-British feeling which, ever since the powers so conferred, has been perpetuating some degree, to this day. The French law was, however, superseded by the criminal law.

During the years 1784-85, the maritime provinces of Nova Scotia and New Brunswick were under special constitutional charters, the latter of New Brunswick meeting at the present Fredericton, during the latter year (1791) was marked by the passage of the Constitutional Act, under which representative government was secured to the people, but steady development of the responsible government in Canada until Sydenham, Metcalfe, Elgin, Monck, and the unwavering devotedness of Lord Dufferin to these principles, serve to make this one of the most interesting epochs of Canadian history. We must pass on yet more rapidly to the historical portion of my paper.

We now come to the period of confederation. On October 10, 1864, the Government met the delegates of Nova Scotia, New B

ince Edward Island, at Quebec, to consider eral scheme of confederation. This was as the "Quebec Scheme." It was the ing of the end—the definitive first step to itish North America Act, the Act of Union, al Act and law, under and by virtue of the Dominion of Canada exists to-day. leration was the necessary outcome and of the partial and unjust basis of representa- hich had so long existed in the country. hstanding its intrinsic excellence, its advan- were not immediately recognised. One by e links in the lengthening chain of federal were welded together. First, Nova Scotia, ew Brunswick, and finally Prince Edward joined hands. These several events ex- over a period of nearly three years more. not until July 1, 1867, that her Majesty's nation declaring the Dominion of Canada omplished constitutional fact was legally ised. "Dominion Day" is now kept as a moration holiday throughout the country. 870, the agies of the Dominion Government isely extended over the vast extent of coun- tuate between the western boundary of o and the Rocky Mountains, then known as t's Land, and since as Manitoba, the district watin and North-West Territories. In 1871, a Columbia joined the Confederation, and 3, Prince Edward Island was added to the Newfoundland, and its dependency, Labra- t all the Imperial possessions on the vast American Continent, now alone remains a colony.

*Confederation*.—The British North America just stated, came into operation on July 1. From that date Canada entered upon the ad—viewed prospectively—most important its history.

l Monck in opening the first Dominion Par- t at Ottawa, November 8, of that year, gave ice to the following memorable words:—"I tulate you on the legislative sanction which en given by the Imperial Parliament to the

Union, under the provisions of which we w assembled, and which has laid the founda- t a new nationality that I trust and believe e long, extend its bounds from the Atlantic Pacific Ocean." The Province of Manitoba mitted into the Dominion May 12, 1870, e Act creating the District of Keewatin nto force shortly after.

## II.—GEOGRAPHICAL.

Dominion of Canada as now constituted— y the Federal Union of 1840, then by the leration Act of 1867, and subsequently by tention of 1870-71 and 1873—embraces principal territorial divisions or provinces, aving a Government and Parliament of its It also includes the North-West Territories, tin District, and the islands of the Arctic and Hudson's Bay, which are politically, as a geographically, annexed to them. It s east and west, from the 51st to the meridian, and occupies a superficial area o one-fifteenth of the land surface of the rather more than the United States, and less than the whole of Europe. In the f population they rank as follows:—

## AREA AND POPULATION OF THE DOMINION OF CANADA.

Province.	Square Miles.	Population in 1871.
Ontario .....	109,480	1,620,851
Quebec .....	188,355	1,191,516
New Brunswick .....	27,822	285,594
Nova Scotia .....	21,731	387,800
Prince Edward Island .....	2,188	94,021
Manitoba .....	120,000	12,328
British Columbia, including Vancouver and other Islands }	890,344	10,586
North-West Territory .....	1,888,000	No returns.
Keewatin District .....	309,077	
Islands in the Arctic Ocean .....	311,700	
Islands in Hudson's Bay .....	23,400	
	3,406,542	3,602,596

The population, according to the Census returns (1881), already made, but not officially announced, is estimated at 4½ millions.

It is with the comparatively narrow strip of settled country bordering on the Atlantic coast, extending through the St. Lawrence and Saskatchewan valleys on and near the proposed route of the Canadian Pacific Railway to the Rocky Mountains and Pacific Ocean—the fertile or food-producing belt—that I propose to deal in this paper.

As illustrating the composite character of the Canadian people, the following table, showing the nationalities of the four old provinces, according to the census enumeration of 1871, is of interest:—

	Ontario.	Quebec.	New Brunswick.	Nova Scotia.
African .....	13,436	148	1,701	6,212
Dutch .....	19,992	796	6,004	2,968
English .....	439,429	69,822	88,598	118,520
French .....	75,383	929,817	44,907	32,833
German .....	156,608	7,963	4,478	31,942
Greek .....	7	7	1	24
Half-breed .....	2	—	—	—
Hindoo .....	8	—	—	3
Indian .....	12,978	6,968	1,403	1,666
Irish .....	550,442	123,478	100,643	62,851
Italian .....	304	589	40	152
Jewish .....	48	74	3	—
Russian, Polish .....	392	186	1	28
Scandinavian .....	696	454	200	283
Scotch .....	328,889	49,468	40,858	180,741
Spanish, Portuguese .....	213	142	223	251
Swiss .....	950	173	64	1,775
Welsh .....	5,282	268	1,086	1,112
Various other origins .....	295	32	1	13
Not given .....	4,508	1,154	373	1,526
Totals .....	1,620,851	1,191,516	285,594	387,800

The Indians belonging to 36 tribes, number a little over 100,000. They form the relic of the four once numerous and powerful families or races of—1. The Esquimaux or Muok; 2. The Déné-Dindgè; 3. The Algonquin; 4. Huron-Iroquois. They are scattered all over the North-West Territories and British Columbia, and constitute a large proportion of what may be called the "landed gentry and freeholders of this vast and promising region."

In the composition of her existing population, Canada is then still peculiarly favoured. Commencing as a French colony, Quebec has over a million of the descendants of the foremost nation

of the Latin race—a people distinguished, like their ancestors, for industry and thrift, combined with a natural courtesy and *bonhomie* which endear them to all. If the French Canadian is not, perhaps, quite on a par with his Anglo-Saxon brother in enterprise, he is certainly more than his equal in those amenities which beautify life, and cast a charm over even the hardships of the backwoods; while in devotion to his country, and loyalty to the sovereign under whom his condition has risen from serfdom to freedom, none can excel him.

**Population.**—The population of Old Canada (Quebec and Ontario), exclusive of Indians, in 1774, was 166,256. In 1806, the population of British North America, which included Newfoundland, had only reached 476,000. Since that time, more particularly since confederation, the growth of population has been very rapid. During the latter period the figures show a relatively greater increase than do the United States. Thus:—

	Inhabitants.	Increase.
1806 .....	476,000	—
1825 .....	681,920	—
1831 .....	1,069,000	24,000 per annum.
1851 .....	2,482,000	70,000 "
1861 .....	3,090,561	70,000 "
1871 .....	3,833,000	—
1881 .....	4,500,000	67,000 "

If the present rate of increase, which is shown to be equal to 1·25 per cent., or 12·5 per 1,000 during the last ten years, is maintained during the next two decades, and it is more likely to advance than otherwise, the population, at the close of the present century, will reach, in round numbers, ten millions. According to the census of 1871, more than four-fifths of the population are native-born.

This rapid growth in population is largely owing to the uninterrupted influx of British immigration. Between 1850 and 1878, a period of twenty-eight years, 684,542 strangers settled in Canada, an average of rather more than 25,000 per annum.

Year.	Settled in Canada.	Year.	Settled in Canada.
1851 ....	25,515	1867 ....	14,668
1852 ....	20,943	1868 ....	12,766
1853 ....	32,295	1869 ....	18,630
1854 ....	38,800	1870 ....	24,706
1855 ....	23,000	1871 ....	27,773
1856 ....	24,816	1872 ....	38,578
1857 ....	33,663	1873 ....	60,060
1858 ....	12,340	1874 ....	39,373
1859 ....	6,300	1875 ....	27,382
1860 ....	7,827	1876 ....	25,633
1861 ....	12,486	1877 ....	27,076
1862 ....	28,798	1878 ....	29,807
1863 ....	26,118	1879 ....	30,717
1864 ....	21,738	1880 ....	35,425
1865 ....	19,413		
1866 ....	10,081		
		Total..	750,864

The forthcoming census returns will furnish us with such vital statistics as will enable us to estimate the precise rate of natural increase in the population of Canada, and these I hope shortly to communicate for a future number of the *Society's Journal*. It is slightly lower than the English rate, and not more than half that of Australia and New Zealand. It will be found, on close investigation, to be not far from 1·10 per cent., or 12 per 1,000. The settlement of the back country, rapid

as that has been, has not thus far kept pace with the flow of population to the cities and towns.

The following list embraces the chief cities, with their population:—

	1871	1881 (Estimated.)
Montreal .....	117,225	160,000
Quebec .....	59,699	75,000
Toronto .....	58,092	80,000
Halifax, Nova Scotia.....	29,582	—
St. John, New Brunswick..	28,805	—
Hamilton .....	27,716	—
Ottawa (Capital).....	21,546	—
London .....	15,826	—
Kingston .....	12,407	—
Winnipeg .....	3,000	12,000
Three Rivers .....	7,570	—
Charlotte Town, Prince Edward's Island .....	7,500	—
Fredericton .....	6,006	—
Victoria .....	4,540	—
St. Hyacinthe .....	3,746	—

It is shown by the Board of Trade returns that, since 1815, no less than 7,000,000 have emigrated from these shores, of whom only 2,550,000 have gone to the Colonies, while 4,400,000 have for ever abandoned their allegiance and become citizens of a foreign country. I think (with Sir Alexander Galt) that this is a most deplorable fact, and becomes the worse if we regard them in the light of helpers of their former fellow-subjects at home.

The chief factor in this continued exodus from our shores is to be found in the over-population of the United Kingdom, and in the absolute necessity of providing against the evils—ever increasing, and daily becoming more threatening—which are traceable to this cause. Emigration, continuous, progressive, and systematic, is the only certain remedy and forms, at the same time, the only boon Canada asks from the mother country.

We have, since 1815, a total removal of population from the British Islands to other countries of the enormous number of seven millions, distributed very nearly in the following manner:—

United States.....	4,400,000
British North America.....	1,350,000
Australia .....	1,000,000
Elsewhere .....	50,000
	7,000,000

The striking and significant fact unfolded by these figures is, that up to 1841, and, indeed, until 1848, the movement of British population to British North America was actually in excess of that to the United States. After 1841, two causes operated to turn the flow of emigration mainly to the United States; the first was the condition of Ireland up to and succeeding the famine, the other was the passage of the Homestead Law and the contemporaneous opening up of the vast prairie States of the Union, which began to attract general notice after 1840.

The latter causes were, I think, much the most important, and to them I believe the United States are indebted for the rapid strides they have made in population and wealth, and the great attraction they have offered to the emigrating classes, not only of the United Kingdom, but also of Germany and of Scandinavia.

*production*.—I have already stated the emigration to have reached seven millions, of which at least four millions have left the United Kingdom since 1852. It will probably interest you to know, notwithstanding this immense overflow, the productive powers of our population have more than supplied the gap. In 1853, the population of Great Britain and Ireland was 27,542,588; in 1879, 36,113, showing an increase of 6,613,525. Considering this enormous increase of the resident population, coincidently with an emigration of 7,000,000 since 1852, it will scarcely, I think, be stated that no more important question can so fully occupy attention here, than the best mode of systematising and directing the outflow of people. Had these four millions remained at home, it is probable that the position of affairs here would have been much more critical, and might have been even seriously dangerous. As an illustration of this, I will refer to the state of Ireland, connected with emigration.

From 1861 to 1870 it averaged	81,858
1871 „ 1875 „	65,893
1876 „ 1879 „	29,898

It does not appear an unwarranted deduction to make that the comparative cessation of emigration, noticeable during the four years 1876-79, intensified the evils in that country, which evidence clearly shows, on the west coast at least, to be traceable to over-crowding. When we only see that congestion of population has followed upon a decline or partial stoppage of emigration, it appears to me that the simplest and the speediest cure will in many districts be found in the systematic encouragement of voluntary emigration. I use the term “voluntary” advisedly; the only principle upon which any Government could act. If experience in the treatment of great subjects has taught us anything, it has taught us that the courses of emigration cannot be regulated by political considerations; and that emigration is, after all, not so much a matter of state policy and Imperial legislation as of local law and rightful selection. Mr. Parnell proposes to make the occupants of the Irish soil owners, and Mr. Bright proposes the purchase of a million acres of waste land in Ireland, its reclamation and drainage, and the division of it amongst 40,000 families, on farms of twenty-five acres a piece, a work which he said would be cheap at 10,000,000. Our contention is that it would be very much cheaper and easier, and therefore more profitable, to spend this money, if money is to be spent, in encouraging emigration to a land where ownership of the soil is easy and its returns sure. Partnership in emigration, which most fitly formed the subject of Mr. McCullagh Torrens’s, M.P., recent address before the Royal Colonial Institute, in order to commend itself to the intelligence and conscience of the nation, must work equally for the benefit of the United Kingdom, the Colonies, and the emigrant—a fact which has been too little borne in mind in recent discussions on the emigration question.

There is still another light in which this pressing and all important theme of migration may be viewed. It is that of trade relations between the mother country and the nearest of her colonies. It will be seen by the Board of Trade

returns that, on an average of the last three years, notwithstanding the recovery of prosperity was more early, every person, and, therefore, every emigrant in the United States, has consumed only 8s. 4d. worth of British manufactures, while in Canada he has consumed 32s. worth; it is, therefore, in the interest of British labour at home, in the proportion of 32 to 8, that emigration should go to Canada rather than to the United States.

I will now, with the aid of the map, do my best to pourtray to you some idea of the magnitude and value of the trust that has been assumed by our trans-Atlantic fellow subjects in undertaking the colonisation and government of the northern half of the great North American continent. Here you have presented a domain nearly as large as all Europe, stretching from the Atlantic to the Pacific Ocean, its southern boundary resting in the latitude of the South of France, and its northern line is washed by the waters of the Arctic Ocean. Possessed of the finest forests in the world, most prolific and profitable fisheries, watered by the most extensive system of fresh-water lakes and rivers, enriched with well-nigh every known variety of mineral, including abundant supplies of coal and iron, and now proved beyond any question to contain the largest area of fertile prairie and bread-stuff producing soil in the world—destined, at no very distant day, to become the granary of Great Britain, and the happy home of millions of our countrymen and women.

The Dominion of Canada is naturally divided into three great divisions—the Atlantic, or Eastern; the Central, or Prairie; and the Pacific, or Western.

The Atlantic division is that which comprehends the older settled provinces of Nova Scotia, Prince Edward Island, New Brunswick, Quebec, and Ontario. It contains almost the entire present population of the Dominion—about four millions, and is the only part of the British possessions in North America to which emigration has been hitherto directed. It may be described as the woodland, or forest section of Canada, and stretches from the Atlantic to the head waters of the great River St. Lawrence, west of Lake Superior.

The Central, or prairie division, containing the new province of Manitoba, and the adjoining north-west territories, extends from the densely wooded Atlantic region to the Rocky Mountains. Commencing with the valley of the Red River, the prairie extends westward over a gently undulating country, clothed with the most luxuriant grasses and beautiful flora, for a distance of a thousand miles to the base of the Rocky Mountains, varying in width of from four hundred to six hundred miles. This magnificent district, watered and rendered accessible in its eastern section by the great Winnipeg and Manitoba lakes, is in its central and western portion traversed by the mighty River Saskatchewan, with fifteen hundred miles of steamboat navigation, and fertilised by many beautiful tributaries issuing from the recesses of the mountains. With some comparatively insignificant exceptions, the prairie division of the Dominion contains probably the largest continuous tract of country in the world adapted to the growth of wheat and other cereals, and peculiarly fitted also for cattle-raising, especially on the western plateau, where cool and

abundant water is combined with an exceptionally moderate climate. Settlement in this section is now exceedingly active, and likely to be continuous. During ten months of 1880 (January to October), the total immigration returns were 17,981.

The Pacific section, known as British Columbia, comprehends the volcanic region west of the Rocky Mountains to the Pacific Ocean, with the magnificent archipelago of islands of which Vancouver and Queen Charlotte's groups are the most conspicuous. Possessing a climate much more temperate than that of Canada proper, British Columbia has an immense extent of land fitted for agriculture, while the mountain ranges which traverse the country are replete with minerals of every variety, and are, it is thought by some, quite as rich as the similar districts of California and New Mexico. Gold to the value of eight millions sterling has already been extracted from the gravel-washing alone, without the introduction of machinery. Vancouver's Island has, so far as known, exclusive monopoly of the coal supply of the entire Pacific coast, from Behring's Straits to Cape Horn; her coal-fields are inexhaustible in extent, and excellent in quality, and, in the future, must make this island the emporium of the China and Indian trade, while its importance in connection with the naval supremacy of England in the Pacific Ocean can scarcely be exaggerated.

**Physical Geography.**—The coasts of the Dominion are everywhere extensively indented. The most remarkable of these indentations form the extensive inland seas known as Hudson's Bay, the Gulf of St. Lawrence, and the Gulf of Georgia. The Hudson's Bay, the Mediterranean Sea of Canada, merits a separate paper, and will, I trust, ere long, find a delineator worthy of its growing importance. It is thus described by Dr. Bell, who has spent five years in exploring its waters and shores:—

"Instead of being, as is usually supposed, a part of the Arctic regions, its nearest shore is more southerly than London, and its farthest still remains within the north temperate zone. On the north-east coast there is little snow in winter, and little rain in summer. The tributaries of the bay are the Nelson, which discharges the waters of Lake Winnipeg, the Winnipeg, about the size of the Ottawa, the Assiniboine, 900 miles long, pouring in from the west; and the Red River, coming 800 miles from the south. All the central part of North America, from Labrador to the Rocky Mountains, drains into Hudson Bay. The largest tributary is the Nelson, about four times the size of the Ottawa, at the capital, then comes the Churchill, the Big River, and the Albany. On the west side of the bay, the southerly winds are the coldest that blow in the winter, and there is less snow and less intense cold in the vicinity of York Factory and Fort Churchill than in more southerly regions. During winter, the temperature improves as one goes from Minnesota northward through Manitoba, and down the valleys to Hudson Bay, and bathing is found agreeable in July, August, and September. On the southern and western shore, unlimited supplies of red and white pine, spruce, white birch, balsam, poplar, aspen, and tamarac are found."

Owing to her remarkable physical configuration and extensive watershed, Canada possesses the largest lake and river system in the world. The volume and surface area of her lakes and rivers are equally remarkable. The hydrographical basin of the St. Lawrence, with the great lakes Superior,

Huron, Michigan, St. Clair, Erie, and alone occupy 330,000 square miles. They largest and purest continuous system of fr in the world, and impart to the Dominion factly unique hydrographical character.

The lake system of Ontario and the e prairie region embraces, among many bodies of water, Great Slave, Great B Athabasca Lakes, Winnipeg, Manitoba pegosis, and Lake of the Woods, Simcoe, and Nipissing.

Next to the St. Lawrence, the most b rivers of the Dominion are the Saskatchewan, Peace, Nelson, Athabasca, Ass Albany, Churchill, and Winnipeg, all fl the vast North-West territory; the C Fraser, and Thompson in British Colum Ottawa, which forms the boundary Ontario and Quebec provinces, and i tributaries the Gatineau, Madawaska, I and Matawan; the Saguenay, Richel Maurice, and Chaudière, in Quebec; the Miramichi, Restigouche, and Petitodidac, Brunswick; the Shubenacadie, St. Ma Have, Avon, and Annapolis, in Nova Scot the York and Hilsborough rivers in Edward Island. Only the better known rivers have been navigated to any com extent with steam craft.

Thus Canada possesses a continuous w from the Atlantic to the head of Lake E and thence, with a few unimportant port "carrys," on to Vancouver's Island, a natu way of trade and travel, unequalled for ex grandeur in the world, and the best, bee cheapest and healthiest emigrant route w American continent.

"Climate," says Professor Ansted, admirable compendium of "Physical Geog "is a very complex matter, and one depen a great variety of conditions." These extent affect and depend on each other may ultimately be traced to certain gener connected with physical geography. The logical service of Canada forms a bran General Department of Marine and Fische is most admirably superintended. The Office and Magnetic Observatory are at and thence daily weather warnings are sent than 600 places throughout the Dominion all speculation on that delightfully exciti ject of ordinary English table-talk is sp Canadians, and the time turned to more p account. It is a matter for regret that the mind, though certainly less abused than i in regard to the climate of Canada, is still and unjustly prejudiced in regard to it among the very healthiest climates in the as is proved by the bills of mortality. It influences the formation of the robust ons and sturdy determined character for w Canadians are conspicuous. Climate, s difficulties attendant on overcoming the i the wilderness, naturally impart great en courage to such a population, and bring those wonderful results of successful i which excite the envy and admiration world.

**Resources and Products.**—Agriculture b chief and abiding interest and industry

tion. That farming pays in Canada is sufficiently proved by the fact that more persons are engaged in it than in any other branch of industry.

Nearly one-half of the whole population, at the last census, were then engaged in agriculture; and this proportion has, I think, been fairly maintained during the past ten years. By way of illustrating the rapidly progressive character of the Canadian farming industry, it is sufficient to state the yield and export of the staple crops at various periods during the past half century. In the average export of wheat did not exceed 50 bushels. In 1850, it had increased to 100, and, in 1880, the grain and green crops amounted to 125,000,000.

During the last 20 years the wheat production has been greatly stimulated, and Canada now produces 40,000,000 bushels, and a total of 170,000,000 bushels of all crops, or about 42½ bushels per acre. When the wheat fields of the new Northwest are fairly under cultivation, say before the close of the present century, Canada will have a great surplus for export of 100,000,000 bushels—sufficient to supply the deficit in the present wheat consumption of the United Kingdom.

Stock-raising, which includes stock-farming, dairy farming—next to agriculture—is the most important industry of Canada, both soil and climate being favourable for its prosecution. As it is well known, it thrives best in the region of summer rains and moderate summer temperature, e.g., in the middle and higher parts of the prairie zone. The high quality of Canadian produce is now everywhere acknowledged. In the west and the eastern townships of Quebec offer, perhaps, the best openings for those wishing to engage in this branch of business. Manitoba and the Northwest Territories will, however, offer special advantages as soon as railway communication is established through them. The quality of wool, mutton, and beef raised on the grasses of the North-West prairies is even finer than that produced in the eastern provinces and townships. Cheese and butter, to the value of 8,500,000 dollars, are annually exported. The production of the principal article advanced from 20,000,000 lbs. in 1850 to 40,000,000 in 1878. Beetroot is now produced in Ontario, and a company has just been formed for its further growth and manufacture in sugar. By recent Act of the Dominion Parliament this branch of industry is exempt from taxation for eight years. The foot-and-mouth disease, and epidemics generally, are unknown throughout the Dominion.

Canada, having an extremely diversified geological formation, is rich in minerals. In the entire (or St. Lawrence) region, the mineral resources are especially extensive. Though every way subordinate to her fertile soil, her grand forests, and prolific fisheries, as a source of wealth, her mineral deposits must, as capital and labour make their influence felt in the country, attract increased attention and development.

No single province except, perhaps, Prince Edward Island, is without mineral deposits. Nova Scotia and British Columbia are rich in coal and the total yield of coal in these provinces for the year ending 1879 amounted to 900,000 tons. The following have been worked:—Gold, silver, copper,

lead (galena), iron (magnetic), hematite (chromic and titanite), coal (lignite and albertite), apatite (phosphate of lime), graphite, mica, barytes, asbestos, slate, gypsum, petroleum, rock salt, antimony, iron pyrites, and manganese. The total exports for 1879 amounted to 4,000,000 dollars, or to rather more than three-fourths of a million sterling.

These minerals are not confined to any one province, but are found deposited in one form or another, and in greater or lesser quantities, in every part of the country, from the Atlantic to the Pacific. We can only mention a few of the more valuable mining districts and their chief productions.

Gold has been found and successfully worked, though in a small way, in British Columbia, Nova Scotia, Quebec, and in the Marmora and Medoc districts of Ontario. The method thus far pursued has been that known as "quartz" mining. The average earnings of miners at the present time is estimated at 700 dols. a year.

Silver is known to exist in several sections of the Dominion. By far the richest deposits thus far found have been on the north shores of Lake Superior, south of the Thunder Bay section of the proposed Canadian Pacific railway. Silver Islet has been pronounced one of the most extensive and valuable silver mining properties on the Continent. Thus far silver mining has been the merest surface scratching.

Veins of argentiferous galena are found in almost every section of Quebec south of the St. Lawrence.

Iron and Coal.—Iron exists everywhere throughout the Laurentian ranges. Nova Scotia takes precedence of all the other provinces in the extent and value of her coal and iron mines. There are some twenty mines in operation on the mainland and the island of Cape Breton, and they yield, on an average, one million tons annually. New Brunswick ranks next. Ontario, Madoc, and Quebec exhibit an annually increasing output of iron, but the difficulty of obtaining coal for smelting purposes, and the substitution, as far as practicable, of charcoal, is found to operate unfavourably to its extension in that direction. The coal mines of Vancouver (British Columbia), give employment to a large amount of capital and labour. Anthracite coal of fair quality is found on Queen Charlotte's Island. The "lignite" formations at "Roche Percé," in the Souris River Valley, in the vicinity of the 49th parallel, are now under survey by Professor Selwyn, whose report may shortly be expected.

Oil.—Petroleum, or coal oil, abounds in South-West Ontario, being largely distributed over the western peninsula.

Copper.—Canadian copper is noted for its purity. Mines have been opened along the shores of Lakes Huron and Superior. The "Bruce" mines of Lake Huron are said to yield copper ore to the value of £50,000 annually.

Salt wells and springs are abundant in New Brunswick.

Peat abounds in Quebec, in the island of Anticosti, and in some parts of Ontario.

British North America contains the most extensive and most valuable forests of timber in the known world. Fully one-half its entire surface is still covered with timber. The value of the timber

annually shipped may be roundly stated at 20,000,000 dols. Only the square timber is exported; the logs are manufactured into lumber at home. Forest conservancy and tree culture are, I am glad to be able to report, at last receiving deserved attention. The average Canadian farmer, like his compeer of the Republic, has hitherto displayed little taste in the management of his farm. He was wont to regard every tree as his enemy, and to ruthlessly hew and hack down every shrub and tree within reach of his stalwart arm. If he settled in the bush, the first thing he did was to clear a space round his house, and then he and his grandchildren went on clearing and clearing, until at last his home stood alone. In certain parts of the United States the law wisely offers a premium for trees grown, and the result is that barren wastes have become living forests, and ghastly homesteads have been surrounded by stately evergreens. Canadians must do the same, if they would maintain the hold which they have so long enjoyed in the lumber markets and ship-building yards of the world.

*Fisheries* rank third in importance among the sources of natural productions in Canada. "From Lake Ontario down to the straits of Belle Isle, a distance of nearly 2,000 miles, there is hardly a mile of coast line," says Rowan, in his charming book, "The Sportsman in Canada," "without a river or stream which affords fair angling." The sea-coast fisheries of Nova Scotia, New Brunswick, and British Columbia produce a handsome revenue to the country, and are capable of almost limitless extension. Compared with last year their produce is valued at about half a million more. The following tables, extending over a series of years, establish the fact that this improvement is not casual or spasmodic, but gradual and permanent. The value of the fish product for 1879 was 13,529,255 dollars, of which one-half was exported. This was an increase of 313,576 dollars over the yield of 1878; for 1877 it was 12,029,957 dollars; for 1876, 11,147,590 dollars. The production in each province of the Dominion was as follows:—

	1876.	1877.	1878.	1879.
	Dols.	Dols.	Dols.	Dols.
Nova Scotia .....	6,029,050	5,527,858	6,131,600	5,752,396
New Brunswick .....	1,953,388	2,133,237	2,305,791	2,554,722
Quebec .....	2,097,667	2,560,147	2,664,055	2,830,396
P. E. Island (840,344)	494,967	763,036	348,122	1,402,301
Ontario .....	437,229	438,223	—	367,183
Manitoba .....	30,590	24,023	—	—
British Columbia .....	104,697	583,432	—	—

The values of the different principal fisheries or products for 1877, were:—

	Dols.
Codfish .....	3,561,199
Herrings .....	1,522,091
Mackerel .....	1,667,815
Haddock .....	475,723
Salmon .....	855,687
Lobsters .....	1,213,085
Fish oils: cod, seal, whale, porpoise, dogfish, &c. ....	524,627

The number of fishery licenses issued in 1880 was 4,334, and it is estimated that fully 250,000 people, or one-sixteenth of the entire population, support themselves on this industry.

### III.—PUBLIC WORKS.

The public works of Canada are on a scale commensurate with her own grand proportions. In truth it may be said that they compare favourably with those of any other country in the world. Their valuation, at the close of 1880, was 42 dols., equivalent roundly to £80,000,000 more than twice greater than the Dominion. Of these works we can only now refer to the railways and canals, believing them to be the most important. The former, which already include forty-six main, or trunk, and branch lines, are rapidly increasing, both in number and value. Among the best known are the Grand Trunk, Great Western, Inter-Colonial, Canada Pacific, and Prince Edward Island, Northern and Central roads. The last-named railway, in connection with the extension of the present railway system northward, from Graveland station, will form a most important through line, which will ultimately connect Halifax and Quebec with Vancouver. Trains are now running westward of Deception Bay and it is announced that the entire line to East Bay (Lake Nipissing) will be completed by December next. The mileage of the railway system in operation and under construction at the close of 1880 was 7,906, a very satisfactory exhibit for a population of less than 4 and a-half millions. Of the character of these lines it is needless here to speak, but to say that as regards both construction and management they compare most favourably with the most popular of the United States railways.

The Canadian Pacific Railway—the largest enterprise yet undertaken by the Dominion—is now in the hands of a syndicate of English and Canadian capitalists, who confidently believed that this great work would be the most extensive, and judged by possibility the most important public work yet undertaken in the colonial soil—will be pushed with the same vigour and so characteristic of our Transatlantic brethren. Its length, when completed, will be 2,600 miles. Of this, as most of you are aware, 264 miles, or 10 per cent., are now under construction, on the Superior and central sections promised before December next, and with the assurance of those who have the best right to express opinion on the subject, that at the close of 1885, communication by water across the continent between this dear mother-land of ours and the far west, will be complete. The "Big Farm," which future generations of her sons and daughters are to make productive, will be complete and in order. The track on certain sections of the prairie country, has been laid at the cost of 13,500 dollars, or less than £3,000 per mile. Practical engineers among us this fact will illustrate the favourable conditions on the whole line between Lake Superior and the Rocky Mountains will be constructed. Terms of the agreement between the Government and the Canadian Pacific Railway Company have not yet been officially announced, but it is the place to discuss the details. Enough, however, is known to us that the least hopeful among us that this enterprise will, ere long, be among the successful ones.

this marvellous nineteenth century, both Government and company are gratulated on the bargain they have secured by the favourable circumstances, been able to secure. What is so unmistakably for the good of the whole nation cannot, in the result, result in pecuniary loss to anybody. The absurd fears which have begun to prevail in home quarters in regard to the creation of a transatlantic railway and land monopoly be entertained. The Dominion Government, be borne in mind, possess an interest in the North-West, far exceeding that to the railway company created by them. Between 100 and 150 millions of acres are of over and above the grant of 25 for the construction of the railway. A reasonable measure will tend to check any abuse of power or improper discrimination on the part of the hands of railway companies and speculators. Moreover, the company is bound by the toll clause of the Railway Consolidation Act, cl. 9, sec. 17, which enacts that "No tolls shall be levied until approved of by the Governor in Council, nor until after two weekly publications in the *Canada Gazette* of the bye-law establishing such tolls, and of the Order in Council giving thereof." It may be remarked in this connection, on the authority of the Dominion Minister's last report, that the railway of the country was never before in so prosperous condition.

— The canals of the Dominion cost £10, or about one-tenth the amount in railways. They need not be more particularly described in this paper. They form the link to speak, in the ever-lengthening chain of continental commerce, and those wishing to rely about them will find the whole subject very fully treated in the comprehensive "Hand-Book of Canada," just announced for publication by Messrs. Silver and Co., of Cornhill, the proof-sheets of which have been courteously furnished and largely availed of in the preparation of this paper.

The enlargement of the whole canal system is in progress, which will enable vessels of all sizes to pass from Lakes Superior, Michigan, Huron, through Lake Erie to Montreal and the Atlantic sea. When completed, the canals of the Dominion will practically extend ocean navigation to the shores of Lake Superior, and thus put our kinsmen in a position to compete successfully with the Americans in the vast and all but unexplored trade of the west and north west. As is well known among freighters, shippers, and men generally, the real competition between the rail and water lines, *e.g.*, between the American and Canadian systems, commences at the mouth of Lake Erie.

The telegraph and lighthouse systems of the Dominion fitly supplement the other branches of public Works Department first referred to. A few years ago the Canadian Government became fully conscious of the great importance of a telegraphic system connecting the islands, lighthouses, and the Gulf of the St. Lawrence together, for the better protection of the fisheries, and the safety of shipwrecked vessels. Not only has this

most humane and prudent scheme been carried out, but a telegraph line from Red River across the "Fertile Belt" to the Rocky Mountains, and thence to Vancouver, has been completed, while a Bill has been granted for its extension thence by submarine cable to Japan, China, and our Indian possessions.

All the most important colonies and dependencies of Great Britain will, by means of this line, be placed in direct and continuous communication with the parent Government, without passing through any foreign hands whatever. The total cost of the cable is estimated at four millions of dollars, or about £800,000, which sum includes the completion of the Dominion land lines.

*Defence.*—The defence of Canada is, since confederation, wholly in the hands of her own sons. The law requires that every able-bodied man may be enrolled in her defence. The active militia force numbers 40,000, and the reserve force 600,000 men. Reporting upon Canada's system and means of defence, Lieut.-Col. Strange, commanding Quebec citadel, says:—"Owing to the peculiar configuration of the southern boundary—on which side alone it is open to attack—few vulnerable points exist. The Intercolonial and Grand Trunk systems, supplemented by the Dominion Railroad system, generally enable the troops and militia to act upon what are practically interior lines."

The trade of the Dominion has made itself felt only within the last fifty years. The first steamer navigated the St. Lawrence waters as early as 1809, but commerce advanced with slow and measured step for more than twenty years after that date. Since 1829 trade has multiplied fifteenfold, a rate of increase fourfold greater than that of its population.

For the first time in the history of the Dominion, says a recent writer, we find an excess of exports over imports to the amount of nearly a million and a half dollars. Our trade with Great Britain, in 1880, was about £16,000,000 sterling, an increase of more than two millions and a half sterling over 1879. Our trade with the States decreased by over a million and a half sterling. Our trade with the West Indies and South America amounted to about £1,500,000, an increase over 1879 of £400,000 sterling. Trade with China and Japan shows an increase of £405,000. The export of manufactures increased by nearly £1,000,000 sterling. In 1879-80 the inward and outward tonnage amounted to 6,786,000 tons against 6,088,558 tons the previous year, an increase of 700,000 tons. Upwards of 113,000 of her hardy sons sail the broad ocean in ships, pulled, masted, and sparred from timber grown in her own grand forests. To sum up this branch of our subject it may be remarked that Canada, with a population of four and a half millions carries on a trade equal in value to that of Great Britain at the beginning of the century, with a population of nearly sixteen millions.

Canada is to-day the fourth maritime power in the world. Her sails are unfurled in every sea, and her hulls are found in every port. At the close of 1880, the register of her shipping included 7,377 vessels, with 1,311,218 tons. Of these, 797 are steam craft, having a capacity of 158,862 tons. The total net value of her shipping is nearly eight millions sterling. Perhaps no readier or safer indication of the growth of Canadian trade can be adduced, than that furnished by the

experience of our common carriers, the great ocean steamship lines. Sixty years ago, the Messrs. Allan commenced sailing ships from Glasgow to Canada, and 28 years ago they built their first steamship, a vessel of 1,500 tons, for the mail service between Liverpool and Canada. Now this has expanded to a fleet of 24 ocean steamships, amounting to over 70,000 tons, while the total tonnage owned by them amounts to very close on 100,000 tons. There are also three other regular steam lines, the "Dominion," "Temperley," and "Beaver," besides occasional cargo steamers which ply between British and Canadian ports. Within the present year, a new steam line, under a Government subsidy, by Canada and Brazil, will open the markets of that vast empire to the varied produce of the Dominion, and it is every way probable that similar relations will shortly be established with France and the Spanish West Indies. Increased steam service is also asked between the maritime provinces and England, for shipment of cattle, &c. Now, a word or two only on a subject of great interest—I may say of principal and interest—the debt of Canada.

*Finance, Debt, &c.*—The entire debt of Canada on 30th June, 1880, was 199,125,323 dols., equal to £40,000,000, reduced by sinking funds and other assets to 156,942,471 dols., or about £32,000,000, equal to £9 9s. 4d. per head, against £46 per head in New Zealand, and nearly £21 in Victoria. The taxation for the present year, Sir Leonard Tilley assures us, will not exceed 22s. 6d. per head, or less than half the average taxation of the Australian Colonies.

The guarantees by the Imperial Government on Canadian account are thus stated in the Finance Account for 1879-80, March 31:—

For construction of railway from Revire du Loup Q. P to Truro, Nova Scotia .....	£3,000,000
Purchase of Rupert's Land .....	300,000
Canadian Pacific Railway and Improvement of Canals .....	3,000,000
By way of security for these guarantees, amounting to six millions three hundred thousand pounds sterling, there is a sinking fund against the first guarantee of ..	358,600
Against the second .....	39,800
Against the third .....	86,400
	484,800
	6,300,000
	£5,815,200

There would, therefore, appear to be a balance of rather more than five and three-quarter millions sterling, the payment of which, by Canada, has been guaranteed by the Imperial Exchequer. The interest on this sum is promptly paid by the Dominion, and Mr. Gladstone has, himself, publicly stated in the House of Commons, that not only has the pledge of the Dominion Government never been violated, but that her credit is to-day stronger than ever.

The national policy, according to Sir Leonard Tilley's last budget report, is, on the whole, worthy of the confidence of its founders. He at least entertains no doubt as to the revenue creating power of the present tariff, or of its ability to meet all the requirements of the country.

The deposits in the Dominion Post-offices and

Savings'-banks afford a sufficiently good the general prosperity of the people amounted in 1878 to nearly nine millions; in 1879 to nearly ten millions, and in 11,688,356 dollars. On the 31st of Janu present year they were 14,730,594 dollar ing an increase of 5,732,481 dollars—mo million sterling—in the peoples' saving added to bank deposits of twelve millions total of 18½ millions of increased deposi the past year.

With these brief and somewhat delivered facts and figures respecting Ca paper must close. The Home Colony is bet such colours as a careful study of her res needs enable me to present. Her past interest. Her future is full of promise. no need to exaggerate her advantages enforce her claims upon the attention and home-loving people. The silken pathy which, for more than one hund has bound the mother country to her nearest, and—may I not add—dearest c shortly be strengthened by the iron bar mon material interest, thus linking tl of ours with the dominion in stronge social and commercial union, for purpos support and defence. Survey our empire and behold our home.

## DISCUSSION.

Mr. Lionel Boyle intended to limit his r portion of the immense Dominion of Cana described in the poetical language of L as "the keystone of the mighty arch stretching across the entire continent from to the Pacific Ocean." It was strange th bilities of so fertile a country should have little known in England, but it had separated from the rest of the world by v ways, and, to some extent, also by the the Hudson's Bay Company to encour emigration to one of the best countries furred animals. Every practical man wh it, including Lord Dufferin, had admitte was no finer or more fertile country in the w said of it that the winters were too long an but they were not so long or so severe as th at all events, in the latitude of St. Peterab severity of her winters had not prevented becoming a great nation. Very strange it the 7,000,000 emigrants from this coun been referred to, so large a proportion gone to the United States, from an id States offered greater advantages to setti own colony, for that idea was erroneous. be some systematic means devised of induc

that grand country, whether by Government enterprise. The relationship of England should be that of a mother to her children; we had had every opportunity of developing enterprise, she had not yet tried her hand. The total emigration from this country in the last 49 years had been 7,782,209, of which £5,228,000, had gone to the United States, America and Australia had only received £500,000 each. Surely it was time that war time might arrive when it would be desirable that what we required should come from our own land and not from the United States, though war was not probable at present, and that could be furnished by Manitoba. Much to promote emigration to our own colony, the United States, by the reading and such papers as they had just heard.

Mr. C.B. agreed with the reader of the urgent necessity of information being diffused amongst all ranks of people as to the value and importance, as well as of our own vast and fertile territories and, however, of recuperating and recruiting transplanting our people to our own land, from lack of proper information and that it might be, in certain cases, of help from Government, drift away to the kindred nation. While it would be rather unfair to attempt to coerce emigration, or to narrow it into any one channel, our policy so far had been fatally neglecting the interests of a nation, and by no means as those who left us as it might have been. As they had heard should be the means of attention from the public and from the Government, the vast and pressing importance of the matter were, he believed, God's best gift to us and needed a large, a wise, and more general policy.

He could not but feel that, to a great use of them now, in the crisis of their day, would depend the continuity of their old home and flag, and our own true nation. Mr. Hall had touched briefly, but on the most pressing and important subject—our defence, of strengthening all essential safety of the whole expanse of British Empire, and might he not add of the empire of England throughout all her dominions. Firstly, and specially called attention to the Channel, and the Pacific Coast. That seemed most valuable, not only from its position and their feeding powers for the naval marine, but from its position on the Pacific, Japan, China, and India. Mr. Hall had touched upon Imperial defence. It was to the Royal Commission now engaged on the subject to meet it in its entirety, and that fuller given them to do so. Having commented for many years in and throughout the history of British North America, he could tell the reader of the paper had said as to composing the defensive force of that colony, finer men, or hearts more loyal to the mother land than in the soldiery of Canada could be here.

Mr. George pointed out that there seemed to be a discontent among those present as to the confederation of the mother country with the colonies, but some practical means of initiating this policy had not been alluded to in his remarks. That policy could only be carried out on the basis of mutual interest between the home and the Colonies. It was absolutely essential under the present conditions of trade with

America, and the physical disabilities under which the Dominion still labours, for us to expect to receive the whole of our American food supply at all seasons, or even, perhaps, at any season of the year, from Canada in preference to the United States. Canada should be treated by us as a part of our own country. The British farmer might be brought some day to regard migration from the mother country to a colony in the same light as he would regard migration from Cornwall to Northumberland, and when once that idea was accepted, emigrants would not be so easily tempted to foreign lands. One danger before us was, that the more valuable Canada becomes (and she was becoming more valuable every decade) the more likely were we to lose her. There was a strong feeling now existing in the United States in favour of the fiscal absorption of Canada. This was well illustrated by a recent article in the *Chicago Tribune*, referring to the policy of Mr. Blaine, and advocating the present time as a good opportunity for "including the whole continent north of Mexico under one system of commercial regulation, whereby one and the same tariff law, the same scale of duties and imports, the same Custom-house rules shall prevail everywhere, alike in the United States and in the Dominion provinces." That was a material danger ahead, involving the probability of a wall of hostile tariffs against us right along the North American seaboard. The panacea for this danger, in his view, was to aim at a Customs union between every portion of the British Empire, as against those parts of the world that would not join us in full and fair commerce.

Mr. Proudes said the valuable paper read that evening would, through the medium of the columns of the Society's *Journal*, extend far beyond those who had had the pleasure of hearing it read, and it was to be regretted that lectures, conveying similar information, were not delivered throughout the provinces and in Ireland for the benefit of intending emigrants. With regard to the history of those earlier explorers of North America, the Cabots, he would point out that there existed quite a literature concerning them, which was not open to the ordinary reader. It was erroneously supposed that they were Italians, but, in fact, they had been traders of Bristol for a generation or two. Cabot's maps, charts, and papers were entrusted to a person who had apparently betrayed his trust, for on the death of the great navigator, it was found they had disappeared. Remembering the rivalry that existed between the Spaniards and Portuguese at that period, it might easily be imagined how those documents came to be suppressed by people whose interest it was to do away with them. From searches in the libraries, however, he had satisfied himself that, however scanty the information on the subject might be, some was to be obtained. Having lived for a long period, as boy and man, in the colonies, he had taken interest in many emigration schemes brought forward for the mutual benefit of the colonies, and of emigrants especially from Ireland. But the right sort of emigrants would never be obtained by Imperial schemes. Without venturing into the forbidden region of politics, as a member of the Colonial Institute, he could say that their motto was "a united empire." If that motto were not acted upon, we should lose the colonies, though not from a want of loyalty in the colonists themselves. He had been one of the midshipmen appointed to the first Victorian war vessel, the steam-sloop *Victoria*, and therefore knew something about colonial loyalty. If the Imperial Government could in any way devote public money to assist emigration, it should be done in a way that would not injure the self-respect of the people, but leave to themselves the choice where they would go. Each colony had at present its own emigration agent in England, trying to get as many passengers and much money as possible; and what was wanted was a national emigration agency, where

people of all classes could go and get unbiased, unprejudiced information, where each particular case would be taken into consideration as to ability, trade, or physical strength, and each person advised to go to the place most suitable for him.

Dr Mann, having alluded to the practical character of the paper, drew attention to the circumstance that the Canadians appeared to be so generally able to occupy themselves in agriculture, a fact of great importance in considering the character of the colony. Then the aboriginal population was 100,000, instead of 700,000, as in such small territories as the Transvaal, or 300,000, as in Natal. That was an important fact for persons seeking to live by agricultural labour. If once a good system of starting emigrants in their new sphere of life could be organized, there would be no difficulty in filling our colonies with a large and prosperous population. The difficulties of colonisation were enormously increased, by having to deal with native populations ready to work for next to nothing. As the facts stood, in Canada there was a large territory of as yet uncultivated land, and no competition with cheap native labour.

The Chairman, in reference to competition with aboriginal labour, said that at any rate the Esquimaux would never be in the way, and even if they should, a more easily civilised people did not exist. He had had experience of them, and had found they were honest, and could be trusted to respect the rights of property, and to do no harm to anybody. It was a fact that their women were more clever than the men, and were always applied to by travellers for information. Their superior intelligence was no doubt attributable to the fact that, unlike other savage races, the Esquimaux did not make their women mere beasts of burden, but left them simply to the performance of their household duties. The nearest Esquimaux were, however, located in a portion of the territory which would not be settled for many years to come. With regard to another branch of the aboriginal population, the Indians of the Saskatchewan territory, to whom lands had been granted by the Canadian Government, were already beginning to cultivate the crops, and to breed cattle. The probable eventual separation of the colonies from the mother country had been alluded to in the discussion, and no doubt the separation would take place when the colonies found it convenient, but we should endeavour to part friends with them, and not try to coerce them, as we unhappily once tried to coerce the United States. They would then remain our friends, and send to us for what they want in preference to other countries. As to the suggested absorption of Canada into the United States, probably the Canadians were no more admirers than himself of the change of Government there every four years, with all its attendant political and financial disadvantages. The country had proved to be capable of raising a very hardy and powerful people. Several generations ago, a colony of Highlanders had gone out to a place called Glengarry, and their descendants had become still larger, more vigorous, and more powerful men, perfectly impervious to the cold, and he might say more Scotch than ever in their enthusiastic maintenance of the national customs. Personally, speaking of climate, he had been more tried here in London during the last ten days by the weather than he had ever been on an Arctic station in British North America. To fairly healthy people, the cold of Canada was stimulating. Physically, the conditions of the country varied, but, in the great fertile belt, the yield of crops was double that in the Western States of America, for whereas in that part of Canada the usual crop per acre was thirty bushels, an average crop in Minnesota, Illinois, and other Western States, gave only fifteen bushels to the acre. In Lower Canada, the French settlers had kept together in families on the same bits of land, which, though

ample for one or two, would not suffice a dozen, and, consequently, a large part of Canada had suffered from over-stocking. The Chewan Valley presented simply a succession of grass and pasture lands. Another point to be noted was the large ship-building trade of Canada. Its vessels were constructed there, and all their ships were built in the Canadas, Nova Scotia, Brunswick. It could not be disputed that the force there was as fine a body of men as exists in the world, accustomed to do everything for the land and they were all naturally good shots, shooting habits having taught them to judge of distance. In conclusion, he proposed a hearty vote of thanks to the lecturer.

Mr. Hall, in reply, said that the subject of migration formed the gist of his paper, and he put Canada specially forward as the wealth source of our colonies. Upon the subject of the colonies of Canada, he was glad they had had the opportunity of hearing General Lowry, an old and tried Canadian force. Had Captain Colomb been present, he would, no doubt, have given benefit of his knowledge on the subject.

General Lowry explained that he had been a gentleman on a bed of sickness, and that he regretted his inability to attend.

Mr. Hall, in continuation, acknowledged that of Mr. Edgemo's remarks on the colonisation and on the possibility of a separation between the colonies and the mother country. Both sides of the international boundary in North America were Englishmen, and, therefore, something like a feeling, if not of political sentiment, might be found among them. No doubt, a kind of general customs, had been attempted in the past, but that in no way showed any desire on the part of the United States to Canada. It was, in fact, much more likely to be incidentally observed, that Canada was the United States. A very friendly compromise sprung up between the two countries since the signing of the Reciprocity Treaty, and a large number of United States, notably in Massachusetts, had its resumption, but the Canadians, he thought, were not ripe for that yet. They were satisfied with the national policy, and would probably remain so many years to come. He had heard at Montreal about annexation two years ago, but for it did not exist among any very great part of the Canadian people, an overwhelming majority were not only intensely loyal to the British flag, but immeasurably opposed to anything like annexation by the United States. As to the nation Cabots, he was aware they were not residents and he was indebted to Mr. Pfounder for further information on the subject. They had always had the credit of being among the best of this wonderful country, especially in the north of the Nova Scotia coast. On the subject of schemes for the colonies, Mr. McCullagh had lately expressed himself in favour of a joint action, and in that way probably the interests of the mother country and the colonies who were our surplus population would be best served. The Commission, to take into consideration the subject of colonial emigration, was what was the place of the present system of emigration, advocating his own particular colony. Having watched the course of emigration during years, he was afraid that in too many instances sent out round points to fill square holes, as a scheme of emigration was urgently needed. Mann had said, it was a great advantage to Canada that the aboriginal population, with labour, numbered but 100,000 to 4,000,000.

key were, however, of some use in that : was very creditable to the Indian

Ottawa Government that they had make such good use of the aboriginal another extensive survey of the Hudson's being now made, and it would shortly ster the navigation of those waters in the year was really practicable. tee have also been opened in several ll further to cultivate an interest in e art among the public, a special ent English and other art needle- re 1800, was organised by the school, e 20th of last month. Before alluding d objects exhibited, we quote a few - Martin Alford's address (1876) on the

history of needlework. She writes, "We have no fragments of classical embroideries, but though the stitches have escaped us, we have the materials employed—the gold, silver, and wools; we know their designs from frescoes, stiles vases, &c. What strikes us particularly is, that the forms are so fine, so graceful, so exquisitely simple, never naturalistic, and mostly similar to those employed in architecture. I said before that we have nothing of classical needlework; our earliest European specimens come out of the shadow of the dark ages, and are of the ninth and tenth centuries. They are all ecclesiastical, with one or two exceptions, such as the Bayeux tapestry, and all ugly. . . . Undoubtedly, the greatest teachers of embroidery have been the Persian, Indian, and Moorish schools. These influenced the Italians in their design and colouring; and there is another Oriental group, the Chinese and Japanese, very clever and imitable in their own distinct lines, but far inferior to the first named, in splendour of colour, power of composition and combination, and in that simplicity and yet effectiveness which is sometimes the highest art. In the exhibition of embroidery, at the Kensington Museum, all these types were well represented, and one thing was worthy of note; after a little study, you found that you could almost always assign its place to each piece of work, and put the right date on it, as surely did the stitch and manner betray the period, as surely as the shadow on the dial marks the time of day."

Formerly, the chief demand for art needlework was from the church, and almost all the specimens of the twelfth, thirteenth, fourteenth, and fifteenth centuries, at the recent exhibition, were ecclesiastical work. The late Dr. Rock wrote of ecclesiastical vestments in England—"No kingdom in Christendom was better furnished with them, and their tissues were of the most beautiful and costly that might anywhere be found; ciclatoun, and baudekin, and every other cloth of gold, either plain or shot with colour, samit and satin, velvet, as soon as it was known, silks after all fashions, damasked, rayed, watered, clouded, or as the term then was, marbled; cloth of Tarvas, and fabrics from Saracenic looms were brought from afar, and put to the service of the liturgy as they came to hand." Some of the finest specimens exhibited were lent by the South Kensington Museum, one of these being the famous Sion cope, which is dated about the year 1250. Besides several copes, there were chasubles, dalmatics, maniples, corporals, and altar cloths. Much elaborate work was at one time lavished upon hearse-cloths or funeral palls:—

"Each virgin soon apply'd  
Her ready skill, and wrought of golden thread,  
A costly net, which o'er a pall they spread  
Of finest silk."\*

Most of the City companies had their palls, which were lent out for the burials of their members and members' wives. One of these, belonging to the Vintners' Company, was exhibited.

At the Reformation, the ingenuity of the ladies was diverted into entirely new channels, and embroidery was used for a very large number of varied objects. Although in the work of the previous centuries there was necessarily a considerable variety of stitch, still the general design remained somewhat similar, as the objects to be ornamented continued the same, but when the needle was free to work for secular objects, a considerable change in treatment became perceptible, and the subjects were adapted to the objects treated. In the reigns of Henry VIII., Mary, and Elizabeth, a very favourite covering for books was embroidered velvet, and this taste was continued for long after their reigns. There was at this Exhibition a Prayer-book and Bible in red velvet covers, embroidered in gold and silver

\* Hooker's translation of "Orlando Furioso," B. xiii.

thread work in relief, with the royal arms, rose and thistle, and C.R. (Charles I.). The nieces of Nicholas Ferrar, who lived at the manor house of Little Gidding, Huntingdonshire, called by the common people the Protestant nunnery, were great proficient in the art of needlework, and they produced a large number of embroidered covers for books, besides many other beautiful objects. Some years ago, three fine portraits in needlework, by these so-called nuns of Little Gidding, were exhibited at the Ironmongers' hall. One of these was of the Virgin Mary, represented as "Queen of Heaven," in an oval wreath, at the angles of which are the pomegranates of Aragon. The second was a portrait of Edward VI., six inches square, and the third a portrait of Queen Elizabeth, of the same size as the second. The greater number of articles exhibited by the School of Needlework in illustration of the work of the sixteenth, seventeenth, and eighteenth centuries are wearing apparel, but in the eighteenth century there were several specimens of embroidered and painted silk and satin work, which were copies of engravings or pictures. In the sixteenth century, English ladies were famous for working carpets, which were used for hangings and table-covers. In 1548, George Lord D'Arcy left to his daughter Agnes, wife of Sir Thomas Fairfax, his "best wrought silk carpet, bordered with crimson velvet, which she made," and Sir William Drury, of Hawsted, County Suffolk, bequeathed to his wife, Elizabeth, "one car্পitt for a cupboard, of those which were of her own making." In addition to the old English needlework, which formed the bulk of the Exhibition, there were some selected specimens of the chief European nations, besides a few pieces of Turkish, Japanese, and Persian work.

#### GLUCOSE MANUFACTURE.

The following particulars respecting the glucose industry, which has grown to large proportions in America during the past fifteen years, are obtained from the *Journal of Applied Science*:—There are at present ten glucose factories in the United States, running day and night, consuming 21,000 bushels of corn per day, each bushel yielding, on an average, 28 pounds of glucose. These figures would indicate a yearly production of over 200,000,000 pounds. That the business is a profitable one, would appear from the fact that it has at least doubled every year for the last five years. Large quantities of the products of the glucose factories are now exported to Europe, manufacturers being able to furnish a cheaper and superior article to that made abroad from potatoes.

The principal object of the originators of this industry in the United States, we are informed, was to manufacture syrup, and from this the application of the products have widely extended. The glucose syrup is not so sweet as cane syrup, and has a lighter colour; and when mixed with the latter it improves its colour, though the saccharine strength or sweetness is impaired. The use of glucose for this purpose has come to be very general, and though even at the present time the business is largely conducted in a surreptitious manner, there are some manufacturers who openly acknowledge that they employ glucose in their syrups, and defend its use for that purpose.

The glucose is likewise largely used by brewers, distillers, and vinegar makers; for sizing paper, for making printers' inking rollers, and other uses. The grape sugar, under which term the manufacturers designate the solid portion of their product, is known to have been for some years quite largely used by confectioners, brewers, and others. Now, however, it is added in the proportion of from 12 to 20 per cent. to cane sugar, and in this form the mixture is brought into the market under the name of "New Process Sugar." As in the case of the corn syrup, the addition of corn sugar to the cane sugars

distinctly improves the colour of the latter, and decidedly reduces its sweetness, which is of a real test of the value of either syrup or sugar. These explanations it will have been made apparent that the colour, which has hitherto been regarded as an indicator of the quality of saccharine products, will no longer be so regarded.

The enormous growth of the business of making and sugar for corn has awakened the very suspicion that these products are extensively adulterating cane syrups and sugars, and sold as such; and there is little doubt but that this falsification is carried on, though to what extent is impossible at present to say. Corn sugar and are not unwholesome; on the contrary, they looked upon as quite as wholesome as cane syrup. The fraud comes in where the corn is which are cheaper and of less saccharine strength, palmed off upon the public for what they are.

#### HEMP CULTIVATION IN MEXICO

The hemp industry in Mexico has, within ten or twelve years, attained considerable proportions. One of the chief articles of trade in Yucatan, is extracted from the hemp plant, or *Amorpha*, commonly called by the Indian name of "hemp." Consul Lespinasse states that the plant is found throughout Yucatan, and forms the basis of the present hemp plantations. The hemp tracks are divided into "pits," which is a Mexican measure of 24 yards square, all the shrubs and weeds have been burned previous dry season, the Indian labourers prepare small pits, in a straight line, from six to eight feet apart, and between each line of pits, a path four feet wide is left clear, in order to give them sufficient room to cut the leaves when they have attained their full growth. As soon as the quantity of land is thus laid out, the young plants are sown close to the ground, and, without any special care, are simply placed in the pits prepared with a little loose earth, and are left to grow of themselves. Each "meccate" contains about 100 plants. Twice a year the ground is cleared of the old plants. As the plant grows, a stem shoots out from the centre, and the leaves gradually detach themselves from it in a spear-like form, with sharp points at the edges, and a strong, black, sharp needle at the point. The plant requires from five to six years to attain its full growth. At the end of the first period, the leaves have an average length of 10 inches. A hemp plant will flourish from 10 to 15 years. A plant has about 26 leaves during the year. In the rainy season, and 10 in the dry; each leaf, long, produces about three-quarters of a pound of fibre; it requires, therefore, from seven to eight thousand leaves to make a bale, weighing five hundred pounds. As soon as the plant has attained its full growth, the leaves are cut from the trunk, from the bottom upwards, only those being left which are well developed. From the hemp is prepared the scarping-machine, which is a strong fly-wheel, on which six or eight knives are placed transversely. The leaves are raised one by one on a curved lever, which is raised in such a manner that the knives on the lever strike the pulp and lay bare the fibre. First of the leaf is presented to the wheel, and as it is scraped the other end is presented. Each time a new leaf is introduced, the other is secured by a set of iron pliers, which are attached to the machine. The machine employs four men, one to place the leaves into the machine, one to attend the lever, one to raise the leaves into the machine, and the fourth to remove the pulp and refuse matter. As

worked by steam-power, and can alone extract pounds of fibre in one day. When extracted from the leaf, it is taken to the and hung on slender poles, which are wooden frames about three feet from the left to dry and bleach in the sun. If the sun, it will become dry in four to five hours; the fibre loses its natural greenish hue, a white, glossy appearance. It is then traulic pressed, and compressed into bales red size, which generally weigh three fifty, four hundred, and five hundred fibre is then ready for shipment.

#### INDUSTRY IN QUEENSLAND.

port on this subject by Mr. Henry Ling are that the crops of sugar in this colony 1879 (that is 31st April, 1879, to 31st to about 18,200 tons, or about 4,500 tons of the previous year. The approximate four sugar districts was:—

rn district .....	about 2,200 tons.
l " .....	5,750 "
7 " .....	9,500 "
Al " .....	750 "

for 1880 is estimated at 21,000 tons, which a low estimate. As far back as 1823, the nas Scott grew the sugar cane successfully drainage of Sir Thomas Brisbane, then l succeeded in obtaining 70 tons in 1827, at e in New South Wales. This venture was th the aid of convict labour placed at Mr. al by the Governor, but, on the removal t, the sugar establishment was broken up. pts were subsequently made to establish astry without effect. Throughout Moreton to its separation in 1859 from New South formation into Queensland, the sugar cane l in the gardens of several people, so that e doubt as to the possibility of its culture. arknow to have been produced in Queens- le by Mr. Buhôt, of Barbadoes, from cane e Botanic Gardens, Brisbane, in May, 63, Captain L. Hope had twenty acres ad the Society of Arts offered a medal for f sugar made in any of the colonies. By 7, there were 20,000 acres under cultivation the six mills in existence manufactured 168

At the close of the season of 1869 there t at work crushing the cane from 1,230 over 5,000 acres under cultivation. In on turned out very bad, the cane, nearly ret, became unhealthy and died, giving eturns. In the course of time the evil i passed away, and the sugar industry has n, more or less of a success. The average r per acre, in Queensland, for the ten 11st March, 1879 (and including the rust as follows:—

district .....	cwt.	qrs.	lbs.
" .....	24	0	25
" .....	24	2	0
" .....	27	0	23
" .....	30	1	2
ad " .....	25	3	0

un may be compared with the yield of e, as in the following table:—

	Average yield per acre.
	lbs.
.....	4,490
.....	1,200
.....	3,600 to 5,600
.....	1,344

Philippine Islands.....	2,800
	(This has been stated as only 1,000 lbs.)
India .....	896
Rio Janeiro .....	2,100
Java .....	about 3,360

Mr. Roth writes respecting these figures:—"According to Porter, virgin land used to give 5,000 lbs. of sugar per acre, and Edwards, in his 'History of the West Indies,' speaks of soil in Jamaica, which with plant cane will produce 2½ tons (5,600 lbs.) of sugar to the acre. Now, in Queensland, 2½ tons and over, or above 7,840 lbs. per acre, have occasionally been obtained from soils newly broken up, but such a yield is exceptional." The manufacture of rum has increased at the same rate as that of sugar. The total production since 1867 was 1,842,322 proof gallons. Up to 1876, the yield was at the rate of over 2 gallons of molasses fermented to 1 proof gallon of rum distilled. For 1877, it was at the rate of 1½ to 1, and in 1878, at the rate of 2 to 1.

The mean consumption of sugar in Australasia is greater than in any other part of the world. The consumption of sugar and molasses in England for 1878 was at the rate of 62½ lbs. per head. Australasia, however, consumed 78½ lbs. per head, or 16 lbs. per head more than England did. Of the colonies, Queensland is the greatest, and South Australia the smallest consumer, their consumption being 92½ and 71½ lbs. respectively. Australia draws her supplies from various quarters. Of the 91,600 tons which went into consumption in 1878, one-sixth was produced by Queensland, and one-twelfth by New South Wales, thus one-fourth of the sugar consumed in Australasia is produced in Australia itself. The remaining three-fourths are imported chiefly from Java and the Mauritius, supplemented by small supplies from the minor sugar-producing countries.

#### A WHOLESOME HOUSE.

"F.R.C.S." has written a letter to the *Times* under this heading, which contains a narrative of his efforts to convert an old London house into a perfectly wholesome and comfortable habitation. His first work was to empty and fill up the cesspools, over which he was living, and connect the house with the street sewer, which had not previously been done. The writer says:—"I had furnished the house in the way common to habitations of its class. There were window curtains in the dining-room, window curtains in the consulting-room, window curtains in the drawing-room, window curtains in the bedrooms. There were carpets on all the floors; there were unprotected papers on the walls; there were wardrobes and other pieces of furniture, which had their apparent height increased by cornices, within which were hollow spaces, seemingly made on purpose to form harbours for dirt. There were ponderous book-shelves, containing a formidable amount of printed lumber, and a still more formidable amount of dust. The walls were old, with uneven surfaces, and to these uneven surfaces dirt clung with an almost touching tenacity. There were all sorts of fluffy things about, which were supposed to be ornamental, fancy mats and the like, and which blackened the fingers of any one bold enough to touch them. Last, but by no means least, there were the ever-increasing accumulations of rubbish, such as old clothes, old toys, old books and pamphlets, old newspapers, old music, and miscellaneous trumpery of every description. Upon all these things the dirt of a London street poured in without intermission. In dry weather the dust found its way through every chink; in wet weather the feet of visitors brought in mud, which dried into dust speedily. If the children romped for ten minutes in a carpeted room, the dust would lie in a thick layer upon the tables and chairs.

when they had finished. Dirt seemed to be omnipresent and all-pervading. It was plentiful in the air we breathed, it mingled with the food we ate, and with the liquids we drank. The principle upon which I started was that the house, for the future, should be kept wholly free from superfluous contents, that all dirt-traps, whether fixed or movable, should be abolished, and that all surfaces should be rendered washable. The first thing was to send away cartloads of the varied material which I have already described as rubbish, the terms including all carpets, all window curtains, all the muslin blinds which people hang across the lower halves of bedroom windows, all books and pamphlets which were not really required, all antimacassars and the like, everything that was broken, and everything that was useless. Having thus cleared the ground, I commenced the work of reform. The first thing, of course, was to see carefully to the drainage and water arrangements, to the ventilation of soil-pipes, the condition of cisterns, and so forth; but in these respects there was not much to be done. The next thing was to cover the old floors with thin oak parqueterie, both in living-rooms and in bedrooms. Upon the parqueterie floors I have a few small Oriental rugs, each of which can be taken up and shaken in one hand. The next thing was to have every unfixed wardrobe, sideboard, or other piece of heavy furniture placed upon castors, so that it might be easily moved by the house-maids, and the wall and skirting behind it kept free from dirt. At the same time the top of every wardrobe and cupboard was levelled by a cover of thin planking or of stretched canvas covered by brown paper, so that all these surfaces could be wiped down frequently and kept perfectly clean. The painted woodwork generally was not only painted, but also varnished; and the wall papers were all varnished, with the exception of one, which was painted. Ventilation is provided for, both in sitting-rooms and bedrooms, by that old system of vertical tubes communicating directly with the outer air, to which attention was recalled some few years ago by Mr. Tobin. Outside the house the external portions of these tubes are bent vertically downwards for a few inches, a method by which the quantity of air-borne dirt which would otherwise enter through them is very materially diminished. In the dining-room the tubes are brought up through ornamental cylinders of Doulton ware resembling vases, but made for the purpose without bottoms, and placed upon wooden plinths of similar construction. In the bedrooms the surfaces of the tubes are painted the colour of the adjacent woodwork; and in some of the upper rooms I have been content with a simple board, about 5in. high, covering the lower part of the window opening, and serving to direct the entering air upwards when the sash is raised to a somewhat smaller extent. With this board the bedroom windows may be left open all night, both rain and direct draught being excluded."

In conclusion, "F.R.C.S." says that he wishes to pay a grateful tribute to Mr. R. W. Edis, from whose Cantor Lectures, delivered before the Society of Arts in 1880, he derived the suggestions which first led him to think of perfect cleanliness as the highest domestic virtue.

#### SWISS CENSUS OF 1880.

The Geneva Correspondent of the *Times* gives the following particulars respecting the recent census of Switzerland, of November 30, 1880. The population of Switzerland on the night of November 30, as given in the official returns, amounted to 2,831,787. In 1870 it amounted to 2,655,001; in 1860, to 2,510,794; in 1850, to 2,390,116. Hence in the first of these decennial periods (1850-60) the yearly increase was 11,219, in the second 14,494, in the third 17,679. In

30 years the population has increased 441,671, equal an average of 14,387 a year. As may be supposed, rate varies greatly in different parts of the country. Some cantons there has been a decrease. One canton Aargau, shows a falling-off in every decennial period since 1840, except in the ten years between 1860 and 1870, and its population is now less than it was years ago. The cantons wherein populations have most increased are Basel city, Uri, Zug, Neuchâtel and Geneva. The population of Basel has risen from 29,555 in 1850 to 64,207 in 1880, an augmentation which is explained by its proximity to Germany and the number of German refugees who have taken their abode in the district. An analogous cause, nearness of Geneva to France, accounts in great part for the fact that the population of this canton has risen from 63,000 in 1850 to 99,000 in 1880. For also many French exiles have taken advantage of the amnesties to return to their own country, and as they have formed connections and attachments in the neighbourhood, and will probably remain there all their lives, the more especially as by doing so they save as well for themselves as their children, the better compulsory military service. The increase in the population of Uri and Zug arises from the presence in those cantons of workmen and others employed on the Gothard railway works. The increase of population in Switzerland at large during the 30 years ending 1880 has been at the rate of 5.50 per 1,000 per year. In the first half of the period in question the increase was rather under this proportion, for the second half it was over. Compared with the rate of increase in other countries, the rate in Switzerland is far from being high. Thus the rate per year per 1,000 in England is 11.1; in Scotland, 9.3; in Denmark, 11.1; Sweden, 10.1; Norway, 8.6; Prussia, 10; Saxony, 15.6; Holland, 8.2; Belgium, 8.2; Italy, 7.1. There are only three European countries in which the progress of population is slower than in Switzerland, namely, Bavaria, 5.4; Ireland, 4.3; and France, 2.3. The natural growth of the population of the Confederation in the time under review—the excess of births over deaths—was 200,828; but the actual increase was no more than 176,786, it follows that the country lost 24,112 individuals by emigration. The real loss, however, was probably not so great, as these figures might seem to imply, for when the census of 1870, the basis of the comparison, was taken, thousands of French people, the remnants of Bourbaki's army, French refugees and others, were included in the count. The report from which I quote enters into a curious calculation as to the economic effect of the emigration of the home population. For instance, between 1870 and 1880, Aargau lost by migration the whole of its natural increase of its population; in other words, although the births exceeded the deaths by 19,000, the population diminished by 400. The population of Aargau increased over and above its natural increase by 13,344, many of the new-comers being natives of Aargau. As young people in Switzerland do not marry about much until they have finished their schooling, it is safe to conclude that the immigrants were on the average at least 16 years old. Taking year with another, it is assumed that a child is brought up to its 16th year for less than 100 francs (£14), which, seeing that the basis of calculation is only £4 15s. 10d. a year, cannot be considered an excessive estimate. But as those 16 grown children were the survivors of 19,000, of whom have cost something, it is considered that the total cost of their rearing ought to be put at £103 for each. Hence Zurich by this, so to speak, made an increment of its population made a gain, or an economy of 34,479,000 francs (£1,380,000) at the expense of Aargau and the other districts that may have contributed to the increase. If we assume, on the other hand, that the migrating Aargauers went to the United States, and adopt the American estimate, which

c equivalent of every new-comer at 800 dolrs. States would be indebted to the little canton with its 198,000 inhabitants, for an additional wealth, between 1870 and 1890, com- £2,120,000. According to a return lately o the Federal Council, the elite of the army in regular training liable at any time to be for active service) is composed of eight with an effective strength of 117,769 men et of these divisions is 11,745, the most 7,052 strong. The landwehr, who, having up a regular course of drill, are mastered inspection only, made an effective force of fence, in case of need, Switzerland could the field fully 200,000 men, all fairly dis- id many of them first-rate shots."

#### WAX PALM IN PERNAMBUCO.

Mr. T. Eaton sends some further particulars this palm, described in the last number of J:—

, or vegetable wax (not Caramba) is the f the leaves of the Carnauba Palm (*Cory-*; natural order, *Palmaceae*), one of the 20 of the Brazilian forests. Its fan-like placed in a tuft at the top of a hard solid ing from 30 to 40 feet in height, the stalks as themselves being 6 or 8 feet in length.

leaves have attained perfection, they are e varnished with a thin coating of vegetable e are then gathered and laid in a cold dry cloths, where they naturally wither and a consequence of the shrinking, the coat of e, and peels off in small flakes, these are from e collected, and it is turned out when melted earthen pans, and then cooled. The lumps ed), are about 3 and 4 lb. each, and bear the e pan in which they have been melted; it is lphur colour, with a lustre between that of e resin, and rather brittle. There were im- : Liverpool, in 1878, 80 tons; in 1879, 13 in 1880, 40 tons, and the value has ranged in. and 55s. per cwt.

#### GENERAL NOTES.

**Museum.**—Mr. Albert Grey, M.P. for rland, has given the following notice:—"On Committee of Supply in Civil Service Estimates ment-office), to draw attention to the inefficient ion now provided for the Patent Museum at ington, and to move that the time has come dding worthy of the nation, and calculated to : manufactures of this country, should be erected rplurals funds that have been derived from taxes e." From Mr. J. Howard's return, ordered 1000, it appears that the excess of receipts over has been since 1886 to 1879 upwards of

clamation in Florida.—It is reported in the ut the Philadelphia capitalists who are about to business tracts of land in the State of Florida e Everglades, have completed their contract with one of the main features of the scheme being the e ship canal across Florida. This project almost spursness that of reclaiming 12,000,000 acres of It would not only shorten the distance between n parts on the Atlantic coast and all European e Orleans, Mobile, and all shipping points on the side, but it would avoid the dangers to naviga- are experienced on the countless bays and coral : southern and south-western coast of Florida.

**Sanitary Exhibition.**—The allotment of space in the International Medical and Sanitary Exhibition to intending exhibitors is being proceeded with, and at the last meeting of the committee the names of 225 exhibitors were registered and approved as follows:—Medical section, 115; sanitary section, 94; miscellaneous section, 16. In addition to the wall space and counter space taken, upwards of 1,200 feet frontage of floor space will be allotted to the above exhibitors, representing an area of no less than 8,000 square feet. This area will be occupied by articles which are said to be strictly within the object of the exhibition. The list of exhibitors already includes the leading manufacturers in Great Britain and Ireland in connection with the medical industries, and the industries connected with architecture and sanitary engineering, and important exhibits are said to be announced from France, Germany, Austria, Italy, Belgium, Holland, Norway, and the United States. The time for receiving applications for space came to an end on Saturday last, 16th inst.

**Resistance to Bending of Tempered Glass.**—At a recent meeting of the Académie des Sciences, M. de la Bastie communicated some data as regards the resistance to deflection of tempered as compared with ordinary glass. It appeared from a first series of thirty-six experiments that:—(1) The elasticity is more than doubled in the tempered glass; (2) single tempered glass possesses a resistance about two and a half times greater than ordinary double glass; and (3) semi-double tempered glass is about three times stronger than ordinary double glass. A second series of forty-three experiments showed that:—(1) While the deflections assumed by ordinary glass are so slight that they cannot be registered, tempered glass deflects to an appreciable extent under a load, (2) tempered plate-glass, varying in thickness from 6 to 18 millimetres (about a quarter to half inch), possesses a resistance 8·67 times greater than that of ordinary plate-glass of equal thickness; (3) tempered unpolished glass is about 5·93 times stronger than ordinary unpolished glass.

**Tobacco from China.**—In his last report from Hankow, her Majesty's Consul writes that the supply of tobacco is so large from the provinces of which the mighty Yangtze-kiang forms the market-road, and the leaf so fine in colour, texture, and fragrance, that merchant after merchant has felt convinced that it ought to form a profitable export, but, though in past years it was sent to America to aid in the manufacture of Havana, and also to England for similar purposes, it has not until quite lately proved a remunerative investment. It is now, Mr. Alabaster believes, used for the manufacture of cigarettes, under the name of Turkish tobacco, and for mixing with various cut tobaccos in this country; but he goes so far as to express his conviction that, when better known, it will be smoked on its own merits. Mr. Alabaster only refers to the unprepared leaf-tobacco, as the prepared article, from the nature of the process it goes through, has a taste somewhat nauseous to the foreign palate. In twelve months, close upon eight million pounds of this leaf tobacco were exported from Hankow in foreign bottoms alone, without taking into consideration the amount shipped in native junks; the estimated value being given at about £120,000.

**Cost of Electric Lighting.**—The following particulars of the cost of electric lighting in the City are given in the *Observer*. In the district allotted to the Anglo-American Electric Light Company (Brush Light), comprising Blackfriars-bridge, New Bridge-street, Ludgate-circus, Ludgate-hill, St. Paul's Churchyard, Cheap-side (western end to King-street), 32 electric lamps, at a cost for the year of £1,410, are substituted for 150 gas lamps, costing annually £850 (including lighting and cleaning), thus making the cost of the experiment in this district but £760 above the ordinary outlay for gas; but, deducting the cost (estimated at £760) of providing and fixing the electric machinery and lamps, and removing the same at the expiration of the contract, the expense, as near as possible, is the same as for gas. In the district comprising London-bridge, Queen-street, King-street, Pooley, Guildhall-yard, Mansion House-street, Royal Exchange, and King William-street, assigned to Messrs. Siemens Brothers, 52 electric lamps (including six large ones) will be employed in lieu of 188 gas lamps. The amount of this contract is £3,729. The sum saved by non-consumption of gas is about £300. The amount estimated for providing and removing the electric machinery and lamps at the expiration of the contract is 1,464, so that the cost, compared with gas, is 6s. 6d.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

APRIL 27.—“Five Years' Experience of the Working of the Trade Marks' Registration Acts.” By EDMUND JOHNSON. THEODORE ASTON, Q.C., will preside.

MAY 4.—“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRICE, M.A. Lord ALFRED S. CHURCHILL will preside.

MAY 11.—“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works). WILLIAM SPOTTISWOODE, LL.D., F.R.S., will preside.

MAY 18.—“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS. Dr. SIEMENS, F.R.S., will preside.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

APRIL 28.—“Impurities in Water, and their Influence upon its Domestic Utility.” By G. STILLINGFLEET JOHNSON, F.C.S. ALLEN THOMSON, M.D., F.R.S., will preside.

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Prof. A. K. HUNTINGTON.

MAY 26.—“Telegraphic Photography.” By SHELFORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

APRIL 29.—“The Building Arts of India.” By General MACLAGAN. ANDREW CASSELL, Member of the Indian Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PRATHE, G.C.M.G., K.C.S.I., C.B.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Four Lectures.

*Syllabus of the Course.*

## LECTURE III.—MAY 2.

Fringes. Twisted thread-work in England in the 15th century. Early designs for plaited and twisted threads. Italian, Flemish, French, and English pillow lace. Laces of primitive design.

## LECTURE IV.—MAY 9.

*Resumé* as to styles of design in hand-made lace. Traditional patterns. Sketch of the development of inventions for knitting and weaving threads to imitate lace. Differences between machine and hand-made laces. Modern hand-made laces at Burano, Bruges, Honiton, &c.

This course will be illustrated by specimens of lace. Diagrams and photographs enlarged will be shown by means of the lantern and oxyhydrogen light.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRIDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## ADMISSION TO MEETINGS.

Members have the right of attending Society's meetings and lectures. Ever can admit *two* friends to the Ordinary and Meetings, and *one* friend to the Cantor Books of tickets for the purpose have to the Members, but admission can also on the personal introduction of a Memb

## MEETINGS FOR THE ENSUING WEEK

MONDAY, APRIL 26TH...British Architects, 9, Condu 8 p.m. Mr. J. Slater, “Electric Light Buildings.”

Institute of Actuaries, The Quadrangle, E. W.C., 7 p.m. Mr. Harald Westergaard, “Mortality of the Danish Clergymen from Medical, 11, Chandos-street, W., 8½ p.m. London and Middlesex Archaeological & Martin's-place, W.C., 8 p.m. Rev. H. “A Dismal Depression in Drapery, 1622.”

TUESDAY, APRIL 26TH...Royal Institution, Albemarle 8 p.m. Prof. Dewar, “The Non-Metals (Lecture I.)

Medical and Chirurgical, 53, Berners-street, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. Walter R. Browne, “Value of Upland and Tidal Waters in prod Anthropological Institute, 4, St. Martin's 8 p.m.

Royal Horticultural, South Kensington, S.

WEDNESDAY, APRIL 27TH...SOCIETY OF ARTS Adelphi, W.C., 8 p.m. Mr. Edmund Jo Years' Practical Experience of the Trade Marks' Registration Acts.”

Geological, Burlington-house, W., 8 p.m. Mackintosh, “The precise mode of and derivation of the Moel Tryfan Shelly the discovery of similar High-level Dep eastern slopes of the Welsh Mountain: existence of Drift-zones showing Prob in the rate of Submergence.” 2. Mr. E. V on a Mammalian Jaw from the Fur Swanage, Dorset.” 3. Rev. J. F. Blake lation of the Upper Jurassic Rocks of those of the Continent.” 4. Mr. A “Fossil Chilostomatous Bryozoa from the Victoria, Australia.”

Royal Society of Literature, 4, St. Martin' 4½ p.m. Annual Meeting.

Sanitary Institute of Great Britain, 9, Cond 8 p.m. Resumed discussion on the A Richardson, “Suggestions for the Manag of Small-pox and of other Infectious I Metropolis and large Towns.”

London Institution, Finsbury-circus, E Annual meeting.

THURSDAY, APRIL 28TH...SOCIETY OF ARTS Adelphi, W.C., 8 p.m. (Applied Chemist Section.) Mr. G. S. Johnson, “Impuri and their Influence upon its Domestic U

Royal, Burlington-house, W., 4½ p.m. 1. A son, “The Influence of Stress and Strain of Physical Forces.” 2. Mr. W. K. I Metamorphosis of Lucifer: a Study in M Antiquaries, Burlington-house, W., 8½ p.m. Society for the Encouragement of Fine Ar street, W., 8 p.m. Mr. J. R. Sawyer, “Processes as Applied to Fine Art Reprod Royal Institution, Albemarle-street, W., Tyndall, “Paramagnetism and Di (Lecture I.)

Inventors' Institute, 4, St. Martin's-place, Royal Society Club, Willis's-rooms, St. J 6 p.m.

FRIDAY, APRIL 29TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Indian Secti MacLagan, “The Building Arts of India.

Zoological, 11, Hanover-sq., W., 1 p.m. An Royal Institution, Albemarle-street, W., e Meeting 9 p.m. Prof. Blackie, “The I Literature of the Scottish Highlands.”

Geologists' Association, University Colleg cussions to Charlton and Blackheath, un tion of Dr. Logan Lobley.

National Health Society, 23, Hertford-stre (Drawing-room Lectures.) Prof. Flea “Sanitary House Inspection.”

SATURDAY, APRIL 30TH...Royal Botanic, Inner-ch park, N.W., 2 p.m. Exhibition of Sprix Royal Institution, Albemarle-street, W., Henry Morley, “Scotland's Part in Englis (Lecture I.)

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,484. Vol. XXIX.

FRIDAY, APRIL 29, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## ART WORKMANSHIP EXHIBITION.

Preparations for the Exhibition of Works of Art and Furniture, at the Royal Albert Hall, are being proceeded with. The available space has been divided amongst the following exhibitors who will afford facilities to exhibitors of high class work which may be considered as accessories of such articles to be shown in company with specimens of art furniture exhibited:—  
Messrs. G. Grace and Son; Morant, Boyd, and Jackson and Graham; Gillow and Co.; and Sons; Howard and Sons; Wright and Sons; Collinson and Lock; Gregory and Co.; and Co.; and Johnstone, Jeanes, and Co. The Exhibition will open on Thursday, 12th inst. at the same time as the General Art Exhibition at the Albert Hall, and it is proposed to keep the Exhibition open until the end of July.

## DOMESTIC ECONOMY CONGRESS.

The 10th of the General Committee of Ladies' Domestic Economy Congress was held at the Society of Arts, Wednesday, the 27th April, Sir Henry C.B., in the chair. Present:—The Duke of Airlie, the Viscountess Harberton, Charlotte Schrieber, Lady Blanche Hosier, Mrs. Cotton, Mrs. Floyer, Mrs. Mrs. Hollond, Mrs. Lecky, Mrs. Mann, Mrs. Miss Cole, Miss Hooper, and Miss Master. Lord Alfred S. Churchill, Major-General C. Cotton, C.S.I., Rev. J. Fawcett, Rev. Newton Price, members of the Executive Committee, were also present.

## PROCEEDINGS OF THE SOCIETY.

## NINETEENTH ORDINARY MEETING.

Friday, April 27th, 1881; THEODORE L.C., in the chair.

The following candidates were proposed for election as members of the Society:—

Allison, Herbert John, 41, Southampton-buildings, Holborn, W.C.  
Baggallay, Henry Charles, 4, Ada's-avenue, Hull, Yorkshire.  
Blakeley, John Holmes, M.A., 23, Popstone-road, South Kensington, S.W.  
Elliott, William St. George, M.D., 39, Upper Brook-street, W.  
Favarger, Henri, 75, Turnmill-street, E.C.  
Heseltine, Francis J., Westminster Palace Hotel, Victoria-street, S.W.  
Inglefield, Admiral Sir Edward, K.C.B., 93, Queen's-gate, South Kensington, S.W.  
Keefe, John, Colquitt-chambers, 6, Colquitt-street, Liverpool.  
Longworth, William, Guildford, Surrey.  
Matthay, George, F.R.S., Cheyne-house, Chelsea Embankment, S.W.  
Ramden, John Carter, Griethorpe-hall, near Filey, Yorkshire.  
Ravenworth, Earl of, 9, Mansfield-street, W.  
Severn, Walter, 9, Earl's-court-square, S.W.  
Snape, William, J.P. (Mayor of Over Darwen), Lynwood, Darwen, Lancashire.  
Sproston, Hugh, Hughville, South Norwood, S.E., and Demerara.  
Thornton, Edward, C.B., Bank-house, Windsor.  
Warren, W. J., Cotford-villa, Bournemouth.

The following candidates were balloted for, and duly elected members of the Society:—

Culley, William Richard, 16, Maryon-road, Charlton, S.E.  
Dale, George Williams Melville, Ellerslie, Nether-street, North Finchley, N.  
Davis, Moses, 27, Welldown-square, E.  
Knight, William Duncan, Avening-house, Greenhill, Hampstead, N.W.  
Mackie, John, 2, Victoria-villas, Queen's-road, Reading.  
Pope, Joseph John, M.R.C.S., 4, South-crescent, Bedford-square, W.C.  
Rowan, Arthur Hill, 6, Westminster-chambers, S.W.  
Thornhill, George, C.S.I., 36, Eastbourns-terrace, W.

The Chairman, in introducing Mr. Johnson, said the subject of trade marks was one of great national, and even international, importance. The system introduced by the new law was entirely new, and the law itself in many points was defective, in not expressing what ought to be done in order to carry out its enactments. Much credit was due to Lord Cairns for the attention he paid to the subject, and the care with which the rules were drawn up, but the matter being entirely new, a great deal was left unprovided for, which experience had shown might and ought to have been enacted. If those present would, at the conclusion of the paper, favour the meeting with their suggestions as to what might be done to carry out the intention of the Act, they would render great service to the commercial community.

The paper read was on—

## TRADE MARKS.

By Edmund Johnson, F.R.S., F.Z.S.

Honorary Secretary of the London Trade Marks Committee.

The law relating to trade marks is founded on an accumulation of judicial decisions of our Chancery Judges, based upon the common law of the land and on principles of equity; and was well established before the Trade Marks Registration Act of 1875 came into operation.

It cannot be too clearly stated that the object of the Act was not to interfere with existing rights or to alter the general law, but, as its name infers, to devise a system of registration for trade marks; and, incidentally, its effect has been to render registration compulsory, by debarring those owners whose marks were not registered before the 1st July, 1876, from the right to institute proceedings to prevent infringement.

I desire to confine my attention, as closely as possible, to the practical experience gained in connection with applications for the registration of trade marks under these Acts; and, in the course of these observations, I shall have occasion to mention some important and leading judicial decisions bearing upon the subject, and to suggest some alterations which, I venture to think, will meet with the general approval of those interested in trade marks.

The Act of 1875 provides for the establishment of a registry. It enacts, *inter alia*, that a trade mark must be registered as belonging to particular goods or classes of goods; that registration of a person as first proprietor of a trade mark shall be *prima facie* evidence of his right to the exclusive use of such trade mark, and shall, after five years from registration, be conclusive evidence of his right to the exclusive use of such trade mark. Section 10 of the Act thus defines a trade mark:—

“For the purposes of this Act, a trade mark consists of one or more of the following essential particulars; that is to say:—

“A name of an individual or firm printed, impressed, or woven in some particular and distinctive manner; or

“A written signature or copy of a written signature of an individual or firm; or

“A distinctive device, mark, heading, label, or ticket;

and there may be added to any one or more of the said particulars any letters, words, or figures, or combination of letters, words, or figures; also

“Any special and distinctive word or words or combination of figures or letters used as a trade mark before the passing of this Act may be registered as such under this Act.”

The Act also contains various provisions as to applications to the Chancery division, for rectification of the register and as to the framing and varying of rules.

The Amendment Act of 1876 extended the prescribed period for registration for one year, and introduced a very important new feature in providing for the granting of certificates of refusal in respect of such old marks as could not be registered under the Act of 1876.

The Act of 1877 extended the date for the registration of marks used in textile industries (Classes 23 to 35) to the 1st July, 1877, or such further date as might, by Order in Council, be determined.

**RULES.**—The first schedule to the Rules, settled and published by order of the Lord Chancellor, contains a list of the fifty classes into which goods are distributed for the purposes of registration, in one or more of which every mark must be registered.

The statement containing the application for the registration of a trade mark must specify the goods with respect to which the mark is to be registered, and in the case of a trade mark used

before the passing of the Act, must particularise the goods in respect of which it has been used, the length of time so used.

Other provisions are contained in the rules in reference to the advertisement of the applicant and notice of opposition, as to which I need here make any special reference. I may only remark that they are framed with ability, and have been carried out by the Trade Marks Registry in such a manner as to merit and secure general satisfaction.

**CLASSIFICATION.**—The classification of goods in respect of which trade marks are registered in fifty different classes has been found on the whole to work well. It was prepared upon the basis of the system adopted in connection with most of the leading International Exhibitions. Some classes are very distinct in themselves, whilst others are necessarily, are somewhat incongruous.

**THE REGISTRY.**—On January 1st, 1876, the office for receiving applications for the registration of Trade Marks was opened at 4, Quality Street, Chancery-lane, under the superintendence of the Commissioners of Patents, Mr. H. Reader, then of the Board of Trade, a gentleman who had acquired much commercial experience during his many years' connection with that department, being appointed Registrar. Some time afterwards, Mr. J. L. Whittle, Barrister-at-Law, was appointed Assistant Registrar, being subsequently succeeded by Mr. McCalmont Cairns. The registry is now permanently established at the Patent-office, Southampton-buildings.

Applications during the first year flowed in rapidly. The number received up to December 31st, 1876, was 3,698, covering a total of 10,384. Of these, 2,204 cotton marks were sent to Manchester. 56 oppositions were made during the first year.

Marks were first placed on the register on October 1st, 1876. The number of marks registered on that date stood at 261, some of which had been registered in more than one class, the total registrations attained was 454.

Meanwhile 47 numbers of the official *Journal of the Trade Marks* have been issued. The first number was published on January 3rd, 1876. The *Journal* specifies the names of applicants, the description of the marks to which the marks have been or are to be applied, and, in connection with old marks, the length of time during which they have been used. Such information is accompanied in every instance by an illustration of the mark, with the exception hereafter referred to. During the first year 4,031 different marks were advertised, giving a total of 4,874 advertisements, many of which being applied for in more than one class.

Particulars of the marks registered are given in the *Journal*. The first list was given in the issue of January 3rd, 1877. Every successive number contained a list of the marks registered since the issue of the preceding *Journal*.

During 1877, the second year, the number of marks tendered for registration was considerably less, thus enabling much attention to be devoted to the marks left over during the preceding year; the registration of which was accordingly proceeded with rapidly, 4,984 being entered on the register by the end of that year.

ience brought to bear by this time also many questions, in regard both to law, which had to be settled by judicial legislation in connection with certain marks necessarily had to remain in pending such decisions in the Courts of law. There were several appeals, and one even to the House of Lords. After the great mass of marks in use in branches of industry had been brought to permit of examination, that any could be made in connection with what was termed under the term of "private" and "common" or "open" marks. This is not confined to the cotton trade, but conspicuously displayed in marks therein. It extends to other industries, and may be specially mentioned the iron which arose the questions settled in case") and the needle trade.\*

be made of the following different modes of registration, as in Barrows's case, where an essential feature is registered, with an

The number of marks advertised in 1877 was 7,907, as against 8,753 placed upon the register. Of the latter, of course, a large proportion included marks applied for during 1876.

In 1878, 3,240 marks were advertised, and 3,687 registered. In 1879, 3,198 were advertised, and 3,118 registered, against 2,417 advertised and 2,752 registered during 1880. The total numbers for the five years thus attained are 21,636 marks advertised, and 18,764 registered\*.

intimation that this feature is protected in a variety of combinations. Registration with a note appended, limiting registration in some way; *re* Mitchell (2); *re* Leonhardt; *re* Kuhn and Co.; *ex parte* Barrows; *re* Jelly, Son, and Jones; *re* Lynght; *re* Rabone; *re* Farina (3); *re* Whiteley (all in Sebastian's Digest of Trade Mark Cases); *re* Sykes (29 W. R.). Registration of essential features only, as in *Orr, Ewing v. Registrar of Trade Marks*, in House of Lords. The decision of the Court of Appeal seems at variance with this decision when, in *re* Royal Baking Powder Co., they refused to register the word "Royal," or the words "Royal Baking Powder," without other details, though the word "Royal" was the only feature in the whole label that could be called distinctive, which, in this particular trade, it appeared to be.

\* The following is a statement of the Number of Trade Marks Advertised and of the Number Registered in each of the 50 Classes of Goods, respectively, during the five years commencing 1st January, 1876, and ending 31st December, 1880:—

During 1876, there were issued 47 numbers of the *Official Journal*; 76 in 1877; 33 in 1878; 27 in 1879; and 26 in 1880. The total for the five years is 209.

There can be no doubt that registration has had the effect of encouraging the adoption of new trade marks. This is shown by the fact that, whilst in the first six numbers of the *Official Journal* the proportion of old to new marks was 633 to 100, in the last six issued during the year 1880, there were advertised but 91 old marks against 365 new. As a matter of course it may be assumed that the bulk of the old marks, that is those in use at the passing of the Act (August 13, 1875), have been tendered for registration in the five years during which it has been in operation. Under the restrictions prevailing with reference to new marks, it may well be claimed that there is thus every prospect of ample distinctiveness in the trade marks of the future.

**OPPOSITIONS.**—In all, during the five years, 287 oppositions have been made. Of these, but a small proportion of cases have been carried into Court, a great number having resulted in compromises between the parties concerned, or by the withdrawal of the original applications.

**REGISTRATION OF SUBSEQUENT PROPRIETORS.**—Under assignment, and by transmission, 135 registrations have been effected during the five years. Some further provision on the subject seems necessary.

I am aware of an instance in which the agent in this country of a Continental manufacturer, under instructions to register a trade mark for his principal, completed the registration in his own name, not omitting, however, to debit the costs to the rightful owner of the mark. Subsequently, on the wrongful registration becoming known, the owner was content with the surrender of the notification of registration previously issued by the registrar, and an assignment of the mark itself. As to the value of an assignment under such circumstances, it is not for me to pronounce, but I venture to doubt whether the registration of what is not lawfully possessed can ever be valid, or any legal assignment of it possible.\*

**CERTIFICATES OF REGISTRATION.**—During the five years, 614 certificates for obtaining registration abroad have been applied for, and 86 certificates for use in legal proceedings. The facilities accorded in procuring foreign registrations have been found of much value in all instances, whilst in some countries, as is well known, registration of British trade marks could not have been otherwise obtained.

**CERTIFICATES OF REFUSAL.**—Up to December 31st last, 212 such certificates had been issued. Although this number is comparatively small, it must be admitted that the value of the certificate to the owners of the marks has in most instances fully warranted the providing for such certificates in the Amendment Act of 1876. I am not aware whether in foreign countries, where the certificate from the registry here is a *sine qua non* to obtain registration by British manufacturers, the certificate of refusal is equally recognised. Certainly it

should be so. The certificate of refusal was, a recognition of the user of the the official statement of the fact that although possibly a valid one, is not registration here under the Act.

**SEARCHES.**—The total number of searches at the registry during the year was 4,801.

**RECTIFICATION OF REGISTER.**—In all, rectifications had been effected prior to December last. This is not astonishing, for when and cost of an application to the High Court is considered, it may be well assumed that effort is made to avoid recourse to such even when involving merely a correction. The registrar has the power at the time of application, both before and after advertising of a mark, to permit any alteration to be placed upon the register, then wholly out of his control and into the hands of the Court. That this should be so in respect of essential and distinctive features of the mark is undoubtedly reasonable; but that the registrar should be empowered to make a material alteration in a registered mark which is such as address, &c., can scarcely be justified. Under proper restrictions and the payment of proper fees no difficulty should be placed in the way of a registered owner making alterations as may be required from time to time upon the register. This is a question which should be dealt with under a new rule, and not by the Court. The Registrar should be empowered to submit it to the sanction of the Commissioners. That the Registrar of the Chancery Division of the High Court should have to be brought into the matter and its ponderous machinery set in motion for a mere trifling alteration in an old label upon the register seems monstrous. In one instance, on a recent date, the registered owner of a mark, desirous of striking out in one the word "factory," and to reduce the size of the label, which his address appeared, and placed brackets, did actually apply to the Registrar for an order. Certainly, under the same motives, the Registrar should be empowered to strike out the word "factory" from a second label, and to alter the type and character of the address, and to likewise obtaining authority to place brackets; and similarly to get rid of the word "manufactory" and vary the address, and so on, label, all for one set of costs. The objection to an application, doubtless, was to obtain a certificate bearing the labels in the amended form for foreign registrations. The applicant, of course, when registering abroad, wishes to protect his labels in the form in which they are now used in the country in which he is doing business. If he obtained the certificate of original registration, the representative certificates would not correspond with the original representations tendered for the foreign registration. The application would be refused; and it would be necessary as a preliminary step to register here.

If a trade mark is incorrectly registered, a person who is aggrieved can apply for the registration to be rectified, and the mark may be altered in whole or in part, or a note appended to the registration in some way. The

\* See *ex parte Lawrence, re East, and re Farina*. 30 W. R.

dwelt upon in a paper on the subject, which, conjointly with Mr. Israel Davis, M.A., Barrister-at-Law, I had the honour to contribute to the International Congress on Industrial Property, held at Paris during the Exhibition of 1878.\*

It is not my intention here to pursue this subject further. I will simply remark that it would be well if the manufacturers and merchants of England would unceasingly exert themselves to bring about an international trade mark law. No country would be more benefited by such a law than our own.

For the purposes of the Trade Marks Registration Acts, the definition of a trade mark became necessary, and, having regard to the preconceived notion that a trade mark consists in any name or device adopted to designate goods, its definition must have been found exceedingly difficult; and it may be mentioned that practice is considered by many to have shown that the definition adopted might have been improved upon.

Certain it is that much of the litigation of the last five years about trade marks has arisen out of this definition, by reason of its restrictive character, and the distinction it creates between old and new marks—old marks being all those in use prior to 13th August, 1875 (the date of the passing of the Act), and new marks all those not used prior to that date.

Prior to the new Acts, the common law recognised as a trade mark, a signature, a figure, a fancy name, or a letter, or a combination of letters or words, or a device. Under the Acts, letters, words, figures, or combinations of letters, words, or figures are only recognised as capable of registration when in combination with a device, mark, heading, label, or ticket.

Let me give some instances bearing upon, and illustrative of, the subject.

#### WORD MARKS AND DECISIONS RELATING THERETO.

—Soon after the Act came into operation, an application was made to register the fancy word, "Aeilyton," which had not been used as a trade mark before the passing of the Act. The Master of the Rolls refused to order it to be registered, holding that only those words which had been used before the passing of the Act as trade marks could be registered; the reason assigned being that, under the definition of a trade mark given in the Act, a new word could not rightly be claimed. The practical result of this decision was to exclude from registration all fancy words invented and first used after the 13th August, 1875. So, while "Anatolia" as to liquorice; "Eureka" as to shirts; "Glenfield" as to starch, and a number of other such words, are all trade marks, it is not now competent for any person to create a new trade mark of any such fancy word. As fancy names are among the best remembered of trade marks, the result is to give to articles so named, and established in use before 1875, an important advantage, and to check the continuation of a system which, in the past, has been proved to possess great commercial value.

Another important restriction on the definition of trade marks was arrived at by the decision, on

the application of Messrs. Mitchell, the pen manufacturers, who had used the alphabet from A to W, as descriptive of qualities of the pens made by them, were known to the trade and the "Mitchell's A," "Mitchell's J," & X., after defining what, for the purposes of the Act, is regarded as a trade mark, the power to add thereto (that is, to mark), "any letters, words, or figure combination of letters, words, or figures," is used throughout. Messrs. Mitchell register all these letter marks separately, but the registrar refused, and the Court upheld the refusal, on the ground that, as the definition of a trade mark in the Act was in the plural, "letters or combination of letters, a single letter or word does not come within the definition, and such a trade mark as could be registered under the Act. This decision has had the effect of excluding from registration all signs and numbers, unless in combination with something else. How far this is going to be doubtful, as another learned judge has said, on this point his decision has been reversed by the Court of Appeal—the Court of Appeal has held that the Act all marks that the Court would have registered before the passing of the Act be registered under the Act, the definition of a trade mark given in the Act applying to new marks. This opinion is based on the idea that the purpose of the Act was to protect property, and that property should be protected by the Act, which could not interfere with property already existing, that its own terms observed as a condition of giving the right of registration. Although the case in which Vice-Chancellor James laid down these doctrines was cited in support of the doctrine, the Court accepted the doctrine, but decided that the purpose of registration, the definition of a trade mark applied to all marks, new or old.

In connection with numbers, I am reminded of some test cases having arisen, but that is not possible for a paper manufacturer, number happens to be 10 or 11, or 12, or 13, or 14, or 15, or 16, or 17, or 18, or 19, or 20, or 21, or 22, or 23, or 24, or 25, or 26, or 27, or 28, or 29, or 30, or 31, or 32, or 33, or 34, or 35, or 36, or 37, or 38, or 39, or 40, or 41, or 42, or 43, or 44, or 45, or 46, or 47, or 48, or 49, or 50, or 51, or 52, or 53, or 54, or 55, or 56, or 57, or 58, or 59, or 60, or 61, or 62, or 63, or 64, or 65, or 66, or 67, or 68, or 69, or 70, or 71, or 72, or 73, or 74, or 75, or 76, or 77, or 78, or 79, or 80, or 81, or 82, or 83, or 84, or 85, or 86, or 87, or 88, or 89, or 90, or 91, or 92, or 93, or 94, or 95, or 96, or 97, or 98, or 99, or 100, or 101, or 102, or 103, or 104, or 105, or 106, or 107, or 108, or 109, or 110, or 111, or 112, or 113, or 114, or 115, or 116, or 117, or 118, or 119, or 120, or 121, or 122, or 123, or 124, or 125, or 126, or 127, or 128, or 129, or 130, or 131, or 132, or 133, or 134, or 135, or 136, or 137, or 138, or 139, or 140, or 141, or 142, or 143, or 144, or 145, or 146, or 147, or 148, or 149, or 150, or 151, or 152, or 153, or 154, or 155, or 156, or 157, or 158, or 159, or 160, or 161, or 162, or 163, or 164, or 165, or 166, or 167, or 168, or 169, or 170, or 171, or 172, or 173, or 174, or 175, or 176, or 177, or 178, or 179, or 180, or 181, or 182, or 183, or 184, or 185, or 186, or 187, or 188, or 189, or 190, or 191, or 192, or 193, or 194, or 195, or 196, or 197, or 198, or 199, or 200, or 201, or 202, or 203, or 204, or 205, or 206, or 207, or 208, or 209, or 210, or 211, or 212, or 213, or 214, or 215, or 216, or 217, or 218, or 219, or 220, or 221, or 222, or 223, or 224, or 225, or 226, or 227, or 228, or 229, or 230, or 231, or 232, or 233, or 234, or 235, or 236, or 237, or 238, or 239, or 240, or 241, or 242, or 243, or 244, or 245, or 246, or 247, or 248, or 249, or 250, or 251, or 252, or 253, or 254, or 255, or 256, or 257, or 258, or 259, or 260, or 261, or 262, or 263, or 264, or 265, or 266, or 267, or 268, or 269, or 270, or 271, or 272, or 273, or 274, or 275, or 276, or 277, or 278, or 279, or 280, or 281, or 282, or 283, or 284, or 285, or 286, or 287, or 288, or 289, or 290, or 291, or 292, or 293, or 294, or 295, or 296, or 297, or 298, or 299, or 300, or 301, or 302, or 303, or 304, or 305, or 306, or 307, or 308, or 309, or 310, or 311, or 312, or 313, or 314, or 315, or 316, or 317, or 318, or 319, or 320, or 321, or 322, or 323, or 324, or 325, or 326, or 327, or 328, or 329, or 330, or 331, or 332, or 333, or 334, or 335, or 336, or 337, or 338, or 339, or 340, or 341, or 342, or 343, or 344, or 345, or 346, or 347, or 348, or 349, or 350, or 351, or 352, or 353, or 354, or 355, or 356, or 357, or 358, or 359, or 360, or 361, or 362, or 363, or 364, or 365, or 366, or 367, or 368, or 369, or 370, or 371, or 372, or 373, or 374, or 375, or 376, or 377, 1530, or 1531, or 1532, or 1533, or 1534, or 1535, or 1536, or 1537, or 1538, or 1539, or 1540, or 1541, or 1542, or 1543, or 1544, or 1545, or 1546, or 1547, or 1548, or 1549, or 1550, or 1551, or 1552, or 1553, or 1554, or 1555, or 1556, or 1557, or 1558, or 1559, or 1560, or 1561, or 1562, or 1563, or 1564, or 1565, or 1566, or 1567, or 1568, or 1569, or 1570, or 1571, or 1572, or 1573, or 1574, or 1575, or 1576, or 1577, or 1578, or 1579, or 1580, or 1581, or 1582, or 1583, or 1584, or 1585, or 1586, or 1587, or 1588, or 1589, or 1590, or 1591, or 1592, or 1593, or 1594, or 1595, or 1596, or 1597, or 1598, or 1599, or 1600, or 1601, or 1602, or 1603, or 1604, or 1605, or 1606, or 1607, or 1608, or 1609, or 1610, or 1611, or 1612, or 1613, or 1614, or 1615, or 1616, or 1617, or 1618, or 1619, or 1620, or 1621, or 1622, or 1623, or 1624, or 1625, or 1626, or 1627, or 1628, or 1629, or 1630, or 1631, or 1632, or 1633, or 1634, or 1635, or 1636, or 1637, or 1638, or 1639, or 1640, or 1641, or 1642, or 1643, or 1644, or 1645, or 1646, or 1647, or 1648, or 1649, or 1650, or 1651, or 1652, or 1653, or 1654, or 1655, or 1656, or 1657, or 1658, or 1659, or 1660, or 1661, or 1662, or 1663, or 1664, or 1665, or 1666, or 1667, or 1668, or 1669, or 1670, or 1671, or 1672, or 1673, or 1674, or 1675, or 1676, or 1677, or 1678, or 1679, or 1680, or 1681, or 1682, or 1683, or 1684, or 1685, or 1686, or 1687, or 1688, or 1689, or 1690, or 1691, or 1692, or 1693, or 1694, or 1695, or 1696, or 1697, or 1698, or 1699, or 1700, or 1701, or 1702, or 1703, or 1704, or 1705, or 1706, or 1707, or 1708, or 1709, or 1710, or 1711, or 1712, or 1713, or 1

the Act of 1875? No reason can be traced, so as I am aware, for placing owners of marks consisting of single letters, or single figures, or a letter and one figure in combination, under so great a disadvantage.

In reply to remonstrances made on behalf of an applicant for the registration of an old word mark which had been refused, the registrar some time ago, with much justice, and, as it must be admitted, with very commendable frankness, wrote, "it was only by a very gradual process that the Commissioners were able to settle the principles which the distinctiveness of marks consisting of words only could be determined." In the early part of the work of the office, many word marks entered upon the register, applications for which, if tendered at a later date, would not have been entertained. For instance, in Class 3 (mostly used as medicines) there are upon the register word trade marks as "Infant's Relief," "Family Salve," "Mother's Hope," "Bosom Friend," and many others of a like character. In December, 1879, granted in connection with the words "Family Salve" as a registered trade mark of the owner, infringed by one who had been in his employ as an assistant. The last, Vice-Chancellor Bacon ordered the deletion of the words "Kitchen Crystal Soap" completed, considering them as "special and distinctive," it being proved in evidence that these had been used as a trademark for twelve years. The registrar had declined to register these words as the application of the owner of the mark, a Philadelphia manufacturer. The same words, singly enough, had already previously been registered, conjointly with a monogram, for a soap manufacturer claiming a user since 1840. To the parties concerned the later practice adopted at the registry may appear as being injuriously as against the later applicant.

It is not really so, however, for it was so all owners of old marks in use prior to August, 1875, to forthwith lodge their applications on 1st January, 1876, when the registry was opened. Having neglected to do so, it is by their default that the opportunity has been lost. The registration, conjointly with signature or device, was to be resorted to in connection with such marks equally as with new ones. It only remains to express the hope that, should future provisions provide for the rehabilitation of the use of word marks, all meanwhile registered under the present system may be recognised retroactively, or their re-registration as words alone provided for.

The class of marks has been still further limited by decisions that have been given on the merits themselves. To constitute a trade mark, it is now held that the mark must not bear any relation to the subject matter in respect of which it is applied, and this whatever period of user may be alleged to it. Thus, "Nourishing Stout" could not be a trade mark, because merely descriptive of the article. But a word such as "Nature," when applied to bitters, being not merely descriptive but distinctive, was held to be a trade mark. The test in each case being, "Is the word distinctive or merely descriptive?" If distinctive, however absurd or far-fetched (and the better), it is a trade mark, and

entitled to protection; if descriptive, it is under no circumstances to be registered. This point was dealt with in the case of Lamplough's Pyretic Saline. Mr. Lamplough claimed the use of the word "Pyretic," but the Master of the Rolls, in the first instance, and the Court of Appeal afterwards, held that there could be no property in an adjective simply descriptive of the quality of the goods sold. In another case a contest arose between the words "Valvoleum" and "Valvoline"; both fancy words, both invented to describe the particular article; but each as a trade mark used in combination with a different device; here it was held that no property existed in either word, as both were only another form of stating that the substance was valve oil.

The effect of the decisions having, therefore, been to limit materially the number of fancy words that could be registered, a further point arose on the use of names as trade marks in cases where the name had been used by various manufacturers, as applied to certain classes of goods, such as the word "Berlin" in connection with wools, "Axminster" for carpets. This point was settled in the case of the word "Alloa," as applied to yarns. An application was made to register the word "Alloa" as a trade mark, by a manufacturer who carried on business at Alloa, and manufactured a species of yarn known in the trade by the name "Alloa." The registrar refused to register this word, and his refusal was upheld on the ground that although the word "Alloa" might have been a trade mark if used to denote the goods of one manufacturer, yet, as it had come to designate not a particular maker's goods, but a special kind of goods made by different makers, it had ceased to be distinctive of the maker, had become descriptive of the material, and so could not be a trade mark.

So great a hardship has the public found the restrictive definition of a trade mark, that every conceivable device is resorted to with the view of obtaining the much-coveted right to use, and if possible to protect, fancy names as trade marks.

A vast number of word registrations have been effected in many classes, the system most frequently adopted being to combine the desired word with the signature of the applicant. In use, such words sometimes appear conjointly with the signature, then, of course, corresponding with the full description on the register; but, in many instances, the fancy word is all that it is desired to use and claim, and the signature is omitted.

The question arises, "To what extent are fancy words protected when so used alone?" Upon this point the decisions of the Court will be most anxiously awaited when the question is tried. The word is on the register; fees in respect of it have been paid; the Act has allowed it to be added to the essential portion of the trade mark, viz., the *fac-simile* signature, but has not distinctly specified whether in being so added it acquires the same protection as the signature or as any trade mark distinctive and complete in itself; whether, in fact, it is at all such a portion of the trade mark as can be protected. Against this, it must be noted that, under the Act, the signature is made the essential particular, the addition of a word or combination of words being merely permissive. The question comes to be whether the registration protects the

purposes of commerce, he considered a trade consisting of a fancy name of far greater than any device. Without altogether agreeing with my friend's opinion, I am certain that a proportion of those interested in trade marks his view, although many urge that the best is to register a device, e.g., an animal, as a and to get the article known to the public "tiger" ale, &c.

Registration is a boon for which the manufacturers of this country had continuously asked for upwards of twenty years. Lord Cairns, as the author of the Registration Act, undoubtedly intended that it should prove of the utmost use, but whilst giving with one hand what was taken with the other new restrictions on commerce should be created.

I have certainly never heard of any reasons which would lead me to be valid or of weight, why a word and fancy word should not be allowed to constitute a trade mark. No confusion can prevail. One desirous of using a name in connection with a particular class of goods, can always ascertain whether such name is already on the register.

**TRADE MARKS AND DECISIONS RELATING THERE TO.**—From the beginning, it was foreseen that many special difficulties would be found to prevent the preliminary investigation of the claims for registration of cotton marks.

The Commissioners of Patents deemed it advisable that a duty of so technical a nature should to a great extent be carried out by gentlemen themselves interested in the trade, and likewise able to draw on local and general experience. In this a committee of experts acquainted with the details of the cotton trade was, with the co-operation of the Chamber of Commerce at Manchester, constituted by the Commissioners of Patents. To this committee was entrusted the duty of investigating the claims upon the marks registered as in use as private property, and so as to determine the meaning of the Act entitled to registration, as distinguished from what were to be considered as open marks outside the scope of the Act. The investigation involved was of a most difficult character, and necessitated the deferring of the investigation into full operation of the Act of 1875, which led for one year under the Amendment Act of 1876, and subsequently from time to time further prolonged, by successive Orders in Council, until July, 1879.

The Manchester committee commenced its labours in October, 1876, having its office at 48, Royal Exchange, Manchester, of which Mr. Joseph Fry was appointed keeper. The committee, in the first instance, proceeded with the examination of the 41,712 marks applied for in Class 24, "Cotton Piece Goods." In their early decisions in regard to combinations of marks being questioned, the examination of the marks could not be completed within the limited date, and this, in a measure, necessitated the extension of time referred to above.

**Manchester Cotton Committee.**—Edmund Ashworth, Esq., President of the Chamber of Commerce, Manchester; A. Bernus, Esq., G. Curdall, Esq., James Chapman, Esq., W. F. Danson, Esq., David, Esq., George R. Davies, Esq., S. A. Fulda, Esq., Schmidt, Esq., C. P. Henderson, jun., Esq., A. J. Hunter, Esq., J. Lappe, Esq., G. Lord, Esq., J. W. D. Mather, Esq., John Potter, Esq., E. Reiss, Esq., S. P. Schillings, Esq., Mitchell, Esq., S. H. Sykes, Esq., A. Wallace, Esq. were in Council, December 12, 1877; June 29, 1878; and May 17, 1879.

At June 30th, 1877, the committee had examined 33,681 marks, leaving 8,031 to be dealt with later.

The number to be examined in the first instance would have been considerably greater but for the United Bleachers' Association having, at an early stage, consented to the withdrawal of the whole of their marks, to the number of upwards of 16,000. These were placed in the category of open marks, thus saving much labour and possibly litigation.

The committee in all held 145 meetings prior to completing the investigation of the old marks.

The total number of marks considered was 44,158, composed thus:—Class 23 (cotton yarn and sewing cotton), 2,490; Class 24 (cotton piece goods), 41,455; Class 25 (other cotton goods), 213.

Of this extraordinary number the remarkably small proportion in the respective three classes passed as capable of registration under the Act was 938, 3,413, and 187, respectively; in all, 4,538 out of 44,158—just over 10 per cent.

Meanwhile the Lord Chancellor had divided Class 23 into two divisions, thus providing for a difficulty which had presented itself in regard to cotton yarn and sewing cotton in consequence of the original classification not having divided cotton yarns from sewing cottons.

Similarly, under a special rule, dated February 20th, 1877, it was provided that cotton marks need not be advertised with illustrations in the *Official Journal*, but that the marks should be on view simultaneously at the registry in London and at the Manchester office for a period of three weeks after they had been advertised in the *Official Journal*, under their mere official numbers, with particulars of ownership and date of user. This period was by some deemed to be very short for opposition to be made, particularly as compared with the minimum interval of three months provided in connection with marks advertised with representations. No difficulty or injustice has, however, been traced to have arisen under this head, no doubt from the fact that the utmost vigilance was exercised by the Manchester committee in the first instance in approving the applications for the marks, which the registry subsequently proceeded to advertise.

The first marks in Class 23 passed into the stage of advertising were announced in *Journal* No. 107 (September 5, 1877); the first in Class 24 in *Journal* No. 152 (November 27, 1878); and the first in Class 25 in *Journal* No. 113 (October 17, 1877).

Registration followed in most instances soon after the expiry of the three weeks' interval, the references to the original representations at the registry and the Manchester office meanwhile made being comparatively few.

The Manchester committee of experts, having divided all the cotton marks into two great classes—the "A" list comprising those in which a distinct private right existed, and the "B" list those that, having been used by more than three persons, had lost their distinctive character and become common or open marks—many complaints arose on the part of persons who were placed on the "B" list, and who alleged that their marks were not public, but private property.

The dispute became complicated by questions as to what was the exact position occupied by the Manchester committee. It was contended by some

applicants that they were only a number of persons who, having a special knowledge of the trade and its marks, were deputed to arrange and classify such marks. Others claimed that in effect the committee was a judicial tribunal—a tribunal of commerce—and that its finding on matters of fact could not be questioned or interfered with, unless it was shown that the committee had acted illegally or wrongfully. Vice-Chancellor Hall adopted the first view, and held that he was at liberty to disregard the decision of the committee, to look at the evidence for himself, and to draw his own conclusions. The Court of Appeal took a different view, holding that the decision of the committee was *prima facie* conclusive. The House of Lords, on appeal, reversed the decision of the Court of Appeal, and affirmed the judgment of the Vice-Chancellor, thus holding that no judicial character whatever belonged to the committee. Lord Blackburn's judgment fully summarises the position.\*

The Courts being at liberty to go behind the decision of the committee of experts, several cases have since arisen in which their decisions have been questioned, and questioned successfully.† Each of the cases, to a great extent, involves questions not of law, but of fact, and depends on the facts peculiar to it. The practical result of the cases is that the decision of the committee is only taken as shifting the onus of proof, and throwing on the person who applies for the order to register the onus of proving his title to the mark.

Interesting and important questions have arisen, questions which cannot be said to be in any way settled. In a recent case, a mark had been placed on the "B" list that had been used for upwards of fifty years by the particular firm who claimed it, and to their knowledge had been used by no one else. But it appeared that various bleachers to whom the manufacturers brought their goods to be bleached were accustomed to ask their customers what kind of finish they would like placed on their goods; did they want "X's" finish, or Y's," or "Z's"? These bleachers kept books containing all the marks of the chief manufacturers, any which they would put, if asked, on goods brought them to be bleached. Could this fraudulent use by the bleacher deprive the manufacturer of his

property in the mark, so as to make it an open one? It would seem that it could. The manufacturer, it is said, ought to be known, and would be taken to be known, that these marks were being so used. It would make any difference if the mark was affixed by the bleacher for export only, and never been used in this kingdom, but only this point seems still to be undecided. It is to be more a question of fact than of law, whether the manufacturers had the mark known, and could they be reasonably supposed to have known, if they had used due diligence? If so, their right would be maintained. In some cases the matter was still further complicated by the fact that the bleachers united together as members of an association, that the association included the bleachers who bleached for each manufacturer. Did the association being in effect the servant of the manufacturer, and being a member of, and what was done by, the association, affect the manufacturer, with notice, so as to constitute acquiescence to him? It would seem to have been held that the manufacturer lost his right. This extension of the doctrine of implied assignment to trade marks, which has had the effect of depriving the owner of valuable mark property, and giving the right to use the mark to the world, seems unjust. The result of its application has been yet worse; for owners of marks, if the Act had not been passed, would have been undisputed both here and abroad, and themselves deprived of valuable property. They have not hunted up and prosecuted cases of infringement. Had not the Act passed they would probably in all cases be able to obtain injunctions to protect their property. Now, with the decision of the Court of Appeal against them, and that decision supported by the public purse, with the aid of officers of the Crown, their chance is small. It is still worse, the Manchester committee has allowed any person to send in any marks he likes, and they took no evidence; they required the applicant to act on the representations sent so that infringers, by merely sending in marks, could infringe, not only depriving the owner of his exclusive rights to their marks, but succeeded in obtaining a legal right to use the mark for the future; for if the mark on the list is common property, the owner's right is gone. Nor did the abuse stop here; in some cases a bleacher had the assurance to be allowed to register a manufacturer's mark, and was allowed to do so. Thus, by the Act passed for the protection of property, the prevention of fraud, the pirate is not only enabled to escape from being punished for his piracy, but to acquire an exclusive right in the property he has pirated.

This is not the worst aspect. The state of affairs is occasionally seen of the Attorney-General, at the cost of the public, acting as the champion pirate. The Commissioners of Patents, in some cases, say they are bound to uphold the decision of the Manchester committee, and, for the sake of opposing any application to the committee, make to have his property restored, and applying to the Court to enforce the same.

\* "It would not be usual, or according to the usual principles of justice, that these persons (the committee) should determine upon a question of property without a hearing. The fact, therefore, that the proceedings of this committee are by rules entirely *ex parte*, in my own opinion, goes very far indeed to show that the opinions of the committee were not meant to be final, even to the limited extent the Court of Appeal thought them binding. But I think it rests with the registrar of trade marks to show that these rules are so framed as to make the decision binding, and I find no words to express that the appeal, especially reserved to the Court by the 62nd rule, shall be clogged by anything more than that weight which common sense requires should be given to the opinion of such a body. If the appellants took proceedings to prevent any one from infringing their firm's trade mark, they would have to make such a case as in the opinion of the Court would outweigh the opinion of the committee. I cannot but think that if they make such a case now, they are entitled to an order."

† One of these cases was *Hoyle and Sons, Limited*, where the British and American flags, with the words "Union is Strength," were ordered to be registered. Another was *Dickinson, Ackroyd & Co.*: a Chinese figure holding a scroll bearing Chinese characters was regarded by the committee as an ordinary mandarin, although claimed as "Ka Kum," a Chinese philosopher. Vice-Chancellor Hall ordered registration. The same judge ordered registration in *Dugdale's* case of a phoenix and demi-griffon, and in *Silvester's* case of a jockey riding, both of which had been placed by the committee in Class "B."

mark, notwithstanding he is placed on the list. If this application was allowed on a *facie* case being made out, the applicant would be brought face to face with his opponent, would oppose the registration, and the case would be tried on its merits; but this is not done. The registrar opposes the application to proceed to the registration. Evidence is collected at public expense, counsel are retained by the party at the public expense on behalf of the applicant, and the edifying spectacle is seen of a protected fraud contending with the honest trader. Moreover, the money used by the registrar in litigation is the money paid by the fair trader to register his mark; and this money is spent in carrying the battle of the unfair trader. Surely carrying the *sic vos non vobis* doctrine to its limit.

An important question arises out of these discussions. Does the old maxim, *Quod ab initio vitiosum non modo convalescere potest*, apply to trade marks? Does fraud give any rights? Strangely it would seem that here fraud, if it does not give rights to the wrong-doer, so as to enable him to be treated on the register as the owner of a pirated mark (a point upon which, so far, there is no decision), yet gives the pirate the right to keep the mark off the register. This has been the practice, and seems hard to believe it to be good law. We are leaving the legal side of the subject, and are now at one point to which attention should be directed, as it is one of considerable practical importance. It is an important question of costs. It has been decided that the Court has no power to order the costs of the preliminary proceedings in any two parties before the registrar, previous to the case being set down for hearing, to be paid by the unsuccessful litigant, or to order the successful party to pay costs if it turn out that his opponent is either wrong in law or vexatious in fact, the latter being the peculiar wording of the Act and the subject of costs. As to private litigation, it is only right that all the costs the successful party is put to should be paid by the unsuccessful, as in ordinary cases, for otherwise encouragement is given to frivolous litigants to bring up to the point where no risk of costs is incurred. As to the registrar; it is only fair that the Crown now both gives and receives this rule should be extended to trade mark litigation, especially when it is borne in mind that out of the fees paid by applicants for registration, that the registrar is enabled to find the costs of litigation.\*

**TRADE LABELS.**—With needle labels difficulties arise to those found in respect of the old cotton labels.

A certain number of gentlemen in the trade were recently invited by the Commissioners of Trade Marks to constitute themselves a Redditch Trade Mark Committee.† marks submitted for consideration attained a total of 2,425, of which, upon investigation, only

677 were passed as private marks, the remaining 1,748 being regarded as "open" or "common" marks.

**SHEFFIELD MARKS.**—The Cutlers' Company of Sheffield, under Section IX. of the Act, and under Rules 46 to 56, have their rights reserved, as was provided under the Merchandise Marks Act, 1862. The registry was to be provided in due course with copies of all Sheffield corporate marks, and the Cutlers' Company, on the other hand, to receive from the registrar copies of all marks tendered in respect of manufactures corresponding with those included in Section II. of the Cutlers' Company's Act, 1860. No new corporate mark can be granted at Sheffield, nor any cutlery mark registered here without mutual concurrence of the registrar and the company. Comparatively but a small amount of litigation has arisen in connection with this class of marks. Registration on the part of Sheffield owners being optional, a number remain unregistered in London.

**COLOUR.**—The Act defines in precise terms what is to be deemed a trade mark. It is silent as to colour, design, outline, or form. Whilst open to use in all colours, and registered in black and white only, the representations lodged with the application can present the particular colour or combination of colours used in trade, thus permanently recording them. In some instances the identity of a mark always used and known under some particular colour (such as Bass' red triangle) is entirely lost when presented in black and white, as printed in the *Journal*. Notwithstanding this, it may justly be urged that the owner is actually better protected by registration without reference to colour. Registered in no colour, he is in fact registered in all colours, whereas if registered in one and only so protected, other colours might be claimed by future applicants. Cotton marks are, in fact, registered in colours as used, the registration being by deposit, and colour in their case becoming an element in infringement.\*

**SIMILARITY OF MARKS.**—Some learned judges seem to consider that, in the case of a contest between two persons as to similarity of trade marks, the Court is bound to regard questions of colour and size, though the registrar disregards these points, as colour is not protected by the Act, and there are no restrictions as to the size of marks. It is said, on the one hand, the Act contains nothing about form or outline; the mischief to be guarded against is the mischief to be done to one person by another in the course of trade, and in the use of these marks in trade. It would narrow the construction of the Act to say that the Court is only to look at the mark as printed in the advertisements, not to look at the mark as it will be used in the course of trade. Against this it is said, if the mark is fairly printed—printed as advertised—it will not deceive. If, however, it is used otherwise, printed in such a way as not to bring out its distinctive features, that would not be a fair printing; that use would not be a fair use. It would not be the use of the design registered, but the use of something else, not the distinctive mark proposed to be registered. In considering the point

\* Rotherham the applicant was put to the costs of a trial on appeal, although he succeeded in both instances.  
† *Needle Committee.*—J. F. Milward, Esq. (Chairman), Avery, Esq., W. H. English, Esq., Thomas H. Harper, Esq., B. James, Esq., Walter Lewis, Esq., Joseph Mogg, Esq., George, Esq., Henry Thomas, Esq., G. F. Townsend, Esq., Esmer, Esq.

\* Judgment of the Master of the Rolls in *re Robinson* 22, W. R. 51.

if registration should be allowed, the Court should not consider whether, by a dishonest use or dishonest printing, the mark could be made such as to deceive, but whether, assuming it was printed and used with the distinctive design still kept up, it is calculated to deceive from its similarity to another mark already registered.

If this latter view, which is that of Lord Justice Cotton, is the true exposition of the law, a very large number of marks that have been refused registration would still be entitled to claim it. But it opens a door to fraud, which would be certainly used by the dishonest trader; and, as the law now stands, facilities for dishonesty are already too plentiful.

The registration of a triangle containing the representation of a church was successfully opposed, it being held that whilst distinct when presented in black and white, the triangle containing the church could in subsequent use be coloured red, and the church thus be so much obscured as to render the mark similar to that of Messrs. Bass. The expression "calculated to deceive," should, it was laid down, always be interpreted in its broadest signification, so as to discourage the evil of imitation and to facilitate remedy.

Another class of cases arose, where two or more persons, in ignorance of the use by each other, had both used the same trade mark for goods in the same class. Could each be registered, or did the use by two persons deprive the mark of its distinctive character, so as to make it incapable of registration? On the one hand, it was urged that as each had used the mark independently of the other, each had acquired a property in it. On the other hand, it was argued that the use by more than one person had deprived the mark of its essential character of distinctiveness, and so it had ceased to be a trade mark. A compromise resulted, the Commissioners of Patents deciding that in respect of the same mark in the same class, three persons might be registered.\* If more than three were proved to have used it, then no one could be registered, as the mark had lost its character of distinctiveness, and ceased to be a trade mark. The applications of this ruling have already been numerous, and if it be possible to take advantage of it to the full extent in the fifty classes, there is the chance of some favourite old mark appearing on the register one hundred and fifty times.

As a result of the comprehensive list of manufactures included in some of the classes, it frequently happens that two or three persons desire the use of the same mark in connection with goods wholly dissimilar, but included in the same class. In such cases I think it might well be left to the registrar, with the mutual concurrence of the persons desiring to use the same mark, to permit them to be entered upon the register, each restricted to his own special manufactures. The following could not, I think, ever come into collision—Patent fuel with beer and wine flasks; knapsacks with wooden tops for bottles; hair plaits with straws for sherry corks; dog whistles with incubating machines;

blind cord with sea water for bathing; and boxes with artificial flowers; mouse traps; rolling pins with bridges and summer houses; tarpaulin with dram flasks, and so on. These, with a multitude of others, are caught under "Miscellaneous" in Class 50.

The registration in the adjoining class (49) of any mark in respect of billiard tables preclude the use of a similar mark for billiard nets. These, again, could never come into collision. Is it desirable to extend to all classes the system of subdivision as adopted in Class 23?

**ANTIQUITY OF MARKS.**—Of the marks advertised, the largest number of those claimed by very old user is claimed, are from Sheffield; those are registered, in most instances, in the 5, 6, 12, and 13. One of these marks dates nearly two hundred years; a large proportion upwards of one hundred years.\* Of those applied for soon after the opening of the register, one, that of Kopke's port wine, is as far back as 1838. Six others trace their origin to a date between one hundred fifty and two hundred years ago; whilst more than thirty marks show a user of upwards of one hundred years. Amongst the oldest marks several registered in the name of the Earl of Saxony (Class 16), dating from the year 1735, the words "The Coffee Mill," registered in the 1st class by Messrs. Berry Brothers, of London, a user of one hundred and fifty-five years. December, 1876. The name "Wedgwood" has been a trade mark since 1776. Some of the Offley's port brands are older still. Croft from 1776. Messrs. N. Johnston and Co. Messrs. Hunt, Roope, and Co. claim upwards of one hundred years user for their wine; Messrs. Taylor, Fladgate, and Yeatman upwards of one hundred and fifty years for theirs. G. brandy mark has a user of one hundred and years; Ruinart's champagne, one of a hundred and fifty years. The words "Singleton's Golden Brand" stand registered in Class 3 with a user of one hundred and two years before 1876. The brand of Messrs. Farquharson, of Aberdeen, carry bearing the date 1694, although under its registration it is only modestly claimed as having upwards of one hundred years' user. One "Chocolat-Lombard" labels dates its user as since 1760. The Kendal tweeds of Messrs.

\* This has been laid down by the Master of the Rolls in his own Court and recognised by Vice-Chancellor Hall. Would the Court of Appeal and House of Lords recognise it as warranted under the Act?

trade marks, or parts of the same, ions of exhibition medals have to be : common to a large class of persons, ot to everybody. A medal can never be ark of any individual.

MARKS EXHIBITION.—For use in the evening, I have, at the request of the ad brought here the volumes consti- it is known as the "Trade Marks " In this collection, each of the : in which trade marks are registered arate volume or volumes, and index. or each particular trade is thus facili- ere are three general indexes to the n, provincial, and foreign and colonial. ition was opened in July, 1877, at hen certain provisions of the Act came ion. The convenient and complete erence which the volumes present has of much service in many leading cases. stances, litigation has been avoided ace by those concerned. Concurrently ming of the exhibition, was commenced tion of *Trade Marks*, a journal, of ty-six numbers were issued. In many is journal is a near approach to the *la Propriété Industrielle Artistique et*

*Littéraire*, edited by Pataille, of Paris, which has done so much service as an exponent of the French law on patents, copyright, and trade marks. In *Trade Marks* the endeavour has been so to deal with the subject as to record as fully as possible, and to comment upon all matters of law and fact, interesting to the owners of trade marks in this country.

The subject of trade marks is by no means new to this Society. It was last brought prominently under notice in a paper read by the present secretary, Mr. H. Trueman Wood, in November, 1875.\* In 1859, Professor Leone Levi read a paper on the subject before the Society, and drafted a Bill to be submitted to Parliament. The late Mr. Arthur Ryland, of Birmingham, about the same time read a paper before the Social Science Association. At this period Sheffield was complaining loudly of the systematic forgery of its trade marks in Germany. Early in 1860, Mr. Bass moved in the matter, and under his instructions Mr. J. Travers Smith submitted a draft Bill to Mr. Milner Gibson, then President of the Board of Trade. In 1861, the late Lord Campbell introduced a Bill in the House of Lords. Mr. Milner Gibson and the Attorney-General, in 1862, introduced the Merchandise Marks Act, and at the same time a Trade Marks Bill was brought in by the late Mr. Roebuck and Mr. Hadfield, the members for Sheffield. The two Bills were referred to a select committee, receiving very full consideration. Mr. Hindmarch, Q.C., and the Attorney-General were adverse to registration, which was provided for under Mr. Roebuck's Bill, but not included in the Government Bill, and recommended that at that stage of legislation it should not be inaugurated. The Merchandise Marks Act, 1862, in the result, was passed, and came into operation in January, 1864. That Act has proved most useful, by its deterrent effect, although the number of cases in which it has been put into operation have been but few. In July, 1863, followed the Exhibition Medals Act, the result of the efforts of a committee constituted here one month previously on my representation to the Council of the importance of taking prompt action. This measure was passed through both Houses of Parliament in seven days. A Trade Marks Registration Bill was again brought in by Mr. Bass in 1866. Another Bill for the same purpose was introduced in the House of Commons in 1868. In 1869, followed the Bill of Mr. John Bright and Mr. Shaw-Lefevre. Mr. Chichester Fortescue (Lord Carlingford), conjointly with Mr. Arthur Peel, made another attempt at passing a Bill in 1873, but equally without success. It was left for Lord Cairns, in 1875, to carry through a measure to effect what had been so frequently before attempted, without result. Registration had always been urged upon the Government by the Associated Chambers of Commerce and other public bodies, but there prevailed a divergence of opinion as to whether legislation on the subject should in the first instance provide for a compulsory or a voluntary system. Many

\* The Registration of Trade Marks." By H. Trueman Wood, B.A. November 24, 1875. *Journal*, November 28, 1875, vol. xiv., p. 17.

+ "On Trade Marks." By Prof. Leone Levi. March 16, 1859. *Journal*, March 18, 1859, vol. vii., p. 262.

influential deputations waited on the successive Presidents of the Board of Trade concerned in the proposed Bills referred to, and on some occasions I remember their being accompanied by Members of the Council and of the Trade Marks Committee of this Society. One such committee on a large scale was formed early in 1866, and on that occasion I had the honour to act as reporter. Soon afterwards Mr. Underdown read a paper\* in this room on the "Piracy of Trade Marks." This was followed by another by Mr. Wybrow Robertson, in 1869.†

In his paper, in 1875, Mr. Wood threw out very valuable suggestions as to the mode in which the then recently passed Act might, with most benefit, be carried out. A Society of Arts Committee was formed, and held several meetings, ultimately submitting certain suggestions as to rules and regulations to the Lord Chancellor. In many respects the rules accord with the suggestions then made, notably as regards the statutory declaration and the mode in which applications are prepared, the subsequent advertising and the interval prior to registration.

The five years that have meanwhile elapsed may be considered as having afforded an ample test of the working of the Act. The rules, as at first settled, have in almost all respects remained unaltered, various additional rules being made from time to time, as circumstances required. The experience gained has left but few points to be dealt with. The present time is opportune for reviewing the result of the working of the Act. The expiry of the fifth year is the date at which the marks first applied for under the third section of the Act, commenced to acquire indisputable title as the exclusive property of the owners. In regard to this, it may be mentioned that the registrar, in July last, wisely called the attention of the Manchester Chamber of Commerce, and other public bodies, to the necessity of their causing an examination to be made of the trade marks registered during the five years then shortly to expire, with a view to taking the necessary steps for preventing any such marks which were of a general nature passing into the hands of individuals whose registrations ought to be previously cancelled. This notification from the registrar, so far as I have been able to learn, did not lead to the combined action which might have been expected. As, however, but comparatively a very limited number of marks have even now passed into the indisputable stage, there is time yet for carefully reviewing the bulk of what are on the register. In the absence of any public functionary to undertake the duty of such revision, I shall myself be willing to co-operate with any associated bodies of traders or individuals interested in taking action in this direction.

Within the limits of this paper it is impossible to deal exhaustively with any of the subjects to which it refers. I have endeavoured briefly to glance at the most important points in the commercial aspect, equally as with those of a legal nature. For what I have said in connection with the latter, I am indebted in a great measure to Mr. Willis-

Bund, Mr. Israel Davis, Mr. Sebastian, and Howard Paddison, who have been concerned in many of the cases to which reference is made. Statistical information, subsequent to what has been already published in the reports of the Commissioners of Patents, I am indebted to the courtesy of the registrar.

The day, I trust, may not be far distant when the Supplemental Trade Mark Act may be passed, the view of varying the definition of a trade mark in such a manner as to embrace an original name among the essential particulars, and that of a letter or figure being registered as a mark, and added to any one or more of the particulars of any new mark. Power, under an Act, might be reserved for the registrar to cancel, after a specified period, all applications completed owing to the non-payment of registration fees.

The mercantile community would gladly avail themselves of the permission to record trade marks under a special system of registration, similar to that adopted in America. In any new Act, it would be like to see such a system provided for.

The rules might, I think, be advantageously varied, by giving the registrar power to register, in respect of trivial alterations in trade marks, without application to the Court, where collision is impossible, to permit mutually consenting persons to be introduced to the same mark in respect of goods of different kind, although comprised in the same class.

My own feeling is that these Acts have inaugurated a new era in the history of commerce. For the outlay of an almost infinitesimal sum, the smallest as well as the largest trader in the kingdom, by the registration of his mark, can secure to himself, his successors, the absolute and exclusive right to use that mark in connection with his goods, and to prevent any particular class of them sold with the mark from being of an unvarying and standard excellence. The public, on the other hand, is enabled to look upon the manufacturer's trade mark as a guarantee of such standard degree of quality that they know he cannot depart, except under penalty of losing both credit and custom. Thus, the mark affords security to the purchaser; and honesty the best policy on the part of the manufacturer.

#### DISCUSSION.

The Chairman said there were probably few persons present who had had experience of trade marks used in this country, and as used by competitors, and if so, he should be glad to give their views. They knew that England for many years enjoyed an almost unique reputation with respect to certain manufactures, such as cotton and woollen goods, and many of the marks of English manufacturers consequently acquired great value in foreign markets. But, in some foreign countries, where the English mark was not recognised as a property, the manufacturer had coolly appropriated it, and then, having acquired, in the native market, a right to the English trade mark, whilst the original owner's mark in England had no protection at all. (Chairman) knew of a case where an English manufacturer had gone to France and asked to be registered his own old mark, but the application

\* On the Piracy of Trade Marks." By E. M. Underdown. April 11, 1866. *Journal*, April 13, 1866, vol. xiv., p. 370.  
† On Trade Marks." By W. Wybrow Robertson. April 21, 1869. *Journal*, April 23, 1869, vol. xvii., p. 14.

because the same mark had been used in France by a Frenchman. If the French maker were to make a claim in this country to register the mark for his class of goods, it would be sufficient for him that it was an old mark used prior to 1875, without where it had been so used, and it was doubtful whether a Britishman could successfully oppose the application because three persons, but not more, were allowed to use the same mark, if an old one. The question might probably arise some day, to what extent did the use of a mark in his own country, entitle him to a declaration that he had used a mark for a certain number of years, so as to obtain registration in England.

A German (solicitor to the Trade Marks Protection Society) said he had had considerable experience in the subject, which was a very complicated one, and he would speak upon off-hand. Mr. Johnson asked it in a very able manner. He might say one or two, however, on the question of the registration of English marks. Recently, laws have been passed for the protection of trade marks in Germany, Holland, and Denmark, but, in the case of the latter countries, there were provisions which made it a hardship to English manufacturers. There were very old marks called cutlers' marks—Sheffield marks—consisting of letters, which had, of course, been registered in England as old marks, but in Germany and Denmark the law did not provide for the use of letters. The society he represented had representations to the authorities of those countries, the Foreign-office, but up to the present time refused to register these marks. In Switzerland, the authorities had seen the justice of registering marks which had received the protection of the law in England. He considered that when these marks were about to be passed in foreign countries, there had been at least some attempt to co-operate with those countries and other countries, so that these marks should not occur. With regard to certificates, though they placed the owner of the mark in the same position as he was before with regard to prosecuting infringers, in foreign countries it had no such effect. If the Courts in England refused protection to the owner of a trade mark, that would be sufficient to entitle him to protection in his own country, and the foreigner ought not to be able to use the mark with impunity, as he did at present. He was very glad to co-operate with Mr. Johnson and any body of gentlemen interested in the subject, the purpose of obtaining an amendment of the law, though he must say it had on the whole worked by three persons should be allowed to register a mark, and not four, he did not understand, and had been so decided. The question of costs was another important matter which ought to be considered.

Mr. Ellis-Bland thought there were one or two points which might be usefully discussed in view of the further legislation. There was first the question of foreign manufactures, which was complicated in those cases in which British subjects have gone to foreign countries and registered fraudulent imitations of English marks, and the question might arise whether such persons should be able to come afterwards and register those marks in England. The main point to which he directed attention was the definition of a trade mark, and the necessity of endeavours to obtain some new and comprehensive definition. This could not be done off-hand, when it was done they ought to have the co-operation of foreign countries in the matter. If they were to use an international law of trade marks, they would have to decide what was a trade mark. He thought that the Act of 1875 had rather introduced difficulties, because now there were no less than three distinct classes of trade mark:—Old trade marks registered under the Act, and old marks not

registered, each of which had different rights attaching to them, and which would be treated differently in English Courts and abroad. Then there were new marks registered, and new marks not registered, and here, again, there were different rights existing. They wanted some comprehensive definition which would include all these. There was another important question which Mr. Johnson had briefly alluded to, viz., the case of special words which described a patent article. He had in his mind the case of linoleum. As he understood the law, it was this:—If a man took out a patent for an article and called it by a fancy name, at the expiration of the patent anybody could make the article and call it by that name, whereas if he registered it as a trade mark, that result would not follow. The question was, ought he to be able to register the fancy name as a trade mark or not? Ought he to obtain a greater monopoly by registering a trade mark than by taking out a patent? Some day the important question might arise with regard to zoedone, and other articles of that description, whether anybody might not make them and sell them under the same name. That question ought not to be left in doubt, but to be decided by legislation as soon as possible. Another point was with regard to piracy, and it seemed to him that as the law now stood, pirates had a great advantage. If several pirates chose to combine and send in representations of a mark for registration, alleging use, which, no doubt, they could do, although it was a piracy, they would deprive the legitimate owner of his right to the mark; and would make what was private property common property. He believed that had been done extensively in the case of cotton marks, and might be done in other classes; and it evidently required some legislative remedy. It had been laid down by the Commissioners of Patents that three marks of a similar character might be registered; that principle had never been recognised by any appellate Court, and some day they might be astonished to find that a mark, registered more than once, had ceased to be distinctive. With regard to British manufacturers abroad, he recollected several cases of cotton marks, where the owners of well-known marks in this country had been refused registration in Germany, because some German manufacturer chose to say that he had used the same mark in some small town in that country, on some reels of cotton. He would suggest that it would be well to bring before the Government, whenever the Trade Mark Act was altered, the importance of endeavouring to come to some agreement with all those countries with which we had trade mark treaties, as to what was a trade mark, and to form a system by which registration in one country should be equivalent to registration in all countries, and by which the mark of a manufacturer should be protected everywhere by the mere fact of being registered in his own country.

Mr. Sebastian said the first remark which occurred to him was with reference to the jurisdiction of the Commissioners of Patents. They gave instructions to the registrar as to the manner in which he should carry out his duties, and in the first case which came before the Court, Vice-Chancellor Malins seemed to think that their decision was final; but it was not held to be so now; and the question really was what their jurisdiction amounted to. There was a case in which they instructed the registrar not to register any marks consisting of foreign words or letters, and he accordingly refused to register the word Todd, which was the name of a maker of watches, and was also an Arabic word, meaning mountain. The Court, however, directed him to register it; the registrar appealed; acting, no doubt, under instructions from the Commissioners, but the Court of Appeal affirmed the decision, and the mark was registered. There the instructions of the Commissioners went for nothing; and this question was of importance with regard to point of three owners registering the same mark. The Commissioners had given

instructions that three persons might be registered, but there was no authority for that in the Act, or in the rules. As Mr. Johnson had suggested, it might be useful if some enlarged powers were given to the registrar with regard to altering the register in unimportant particulars, without an application to the Court, though he had not the same dread of that process as Mr. Johnson seemed to have. Enlarged powers might also be given to the Court for rectifying the register. One member of the firm carrying on a very extensive business, registered the firm's trade mark in his own name, for the benefit of the firm, the other partners co-operating with him, and it was held that that registration could not be transferred into the name of the firm. He thought too much attention was paid to the office fees; and with regard to costs, the Court had looked rather too tenderly after the interests of the office. When the Court reversed the decision of the registrar, and ordered a mark to be registered which he had refused, he not only paid no costs, but was paid his own. He (Mr. Sebastian) thought it was a mistake that fancy names should not be registered, as they were in almost all foreign countries, and as they were here in the case of old marks. Of course there was the difficulty which had been mentioned with regard to patent articles under fancy names obtaining greater protection than the Patent-law allowed, but there might be a power of discriminating between fancy names which would become descriptive of the article and those which could not become so. As to the custom which had been referred to, of registering fancy names in connection with a signature, it was to him very difficult to understand how words registered under such circumstances could be protected. The Act said that a trade mark should consist of certain essential particulars, in which these fancy names were not included, though a signature was, and it went on to say that, to such essential particulars, certain immaterial matters might be added. He did not understand how an immaterial addition could be protected. A great many people thought they ought to be protected, but the question was whether they were so at present. In the only decision yet given by the House of Lords on the Act, it was held that such immaterial additions to the signature ought not to be registered. It had been suggested that the object might be attained by registering a device, such as the head of some animal, thus causing the article to acquire the name of the animal; and a very recent case had shown the force of that observation. One man registered a bulldog's head, and another used a terrier's head, but the article to which the mark was attached had become known in the market as dog's head ale, and the result was that one dog's head excluded from registration another dog's head, which was totally different.

Mr. E. J. Wetherston said that it appeared to him that the gist of the able paper they had listened to was contained in the concluding paragraph, just as that of most petitions was contained in their prayer. The moral, both of the paper and the discussion which had followed, proved most conclusively the necessity for a Minister of Commerce. This subject had been discussed, time after time, not only by the Society of Arts, but also by the Social Science Association, and by the various Chambers of Commerce throughout the country. The fact was that Parliament had no time to discuss questions of trade interest. It was necessary, therefore, that such subjects should previously have been considered by a Government department, and that a proper digest should be prepared by those best calculated to frame legislation. There were two Bills now before Parliament of a similar character, in regard to Copyright and Patent-laws, which should be considered together with the laws relating to trade marks. In compliance with the expressed desire of the author of the paper and a previous speaker, he would, as a member of the Council of the National Chamber of Trade, offer the services of that association, by whom an effort would be made to give effect to the

proposals contained in the paper, in order that an opinion might be formed upon the subject.

Mr. Israel Davis was much gratified at finding necessity for unifying the definition of a trade mark throughout the world so generally recognized. He did not know whether any practical suggestion had been thrown out how this could be accomplished, but a precedent existed in the action of one of the Government departments, in carrying out a similar object. It was necessary to introduce a uniform code of signals, and that had been done amongst all the nations of the world which had any commerce, by the action of the Board of Trade. After long and complex negotiations, a general code of signals and a uniform code of signals had been adopted, to which all gave in their adhesion, and not only was effected once, but afterwards, when it was necessary to change the rule of the road, negotiations were set on foot, and the rule changed with unanimous concurrence. This precedent was an encouraging one, and tended to show it was not impossible to attain the great object of a uniform definition of a trade mark, which should be the industries of all the countries of the world. What they should adopt the suggestion thrown out by Mr. Willis-Band that registration in one country was equivalent to registration in all, was another question, and he should be inclined to dissent from that. It would be very hard that a trader in Spain should be bound to know all the marks which existed in the London register, or that a trader in Paraguay should be bound to know of all the marks existing in Melbourne, nor was it at all necessary that marks should be registered in foreign countries. Many trade marks were used for articles which were only used in the vicinity of the manufactory, and others went all over the world; and there might be a different scale of fees for marks used in the home trade, and for those which should be used in all the countries which belonged to the trade convention. That point, he thought, might be left to the care of itself. The first step would be to get the Board of Trade to endeavour to obtain a universal definition of a trade mark; and he thought the Society of Arts might usefully bring the matter before the Government. Allusion had been made to unregistered trade marks, and the certificate of refusal, which was found to be so efficacious in foreign countries as might have been expected. Here it left the manufacturer free to take an action against an infringer, but, abroad, it did not furnish that evidence of title which the foreign registration office required. It occurred to him that a simple alteration would meet the difficulty. If the mark could be altered, so that instead of giving a certificate of refusal, the office issued a certificate of registration without prejudice, or of provisional registry, or of kind of certificate showing the mark was in a different class from others, but still that it had been registered, he thought the difficulty would be got over.

Mr. Johnson, in reply, said he was sorry to hear Mr. Salaman that so much difficulty existed in the United Kingdom and Denmark. He quite agreed with Mr. Davis that the form of certificate of refusal might be improved, but at present it was a most bald document, simply stating that registration had been refused, with no explanation. One could well understand that, when presented to a foreign Court, so far from being of any service in establishing the authenticity of the mark, it acted prejudicially. It might, at any rate, be altered so as to show on the face of it why it was given, instead of a certificate of registration, that the mark was not registered simply as the result of accident, rather than from any impropriety in the mark itself, or any want of originality on the part of the owner. He thought countries which had lately introduced registration of trade marks might reasonably have provided for safeguarding all the

in other countries, and, in fact, have confirmed they ought, as juniors in the matter, to have their seniors, and thrown no obstacles in the way they recognised elsewhere. Mr. Bund's remarks summarise of pirates were very important; not that such combinations really had occurred strongest possible reason for the matter being

The distinctions between old and new marks are only most complicated, and as there were so many kinds of marks, it was really very hard to know what was a trade mark, and what was a question of costs, to which Mr. Sebastian led, was one on which the public felt very hard that the refusal of the registrar, as informality, or some peculiarity in the interpretation of the Act, should involve an application to the Court, and, if the registrar persisted, and, finally, an appeal to the House of Lords, yet that the unfortunate applicant, though he should have to pay three sets of costs twice as much as reference to fancy names, Mr. Sebastian was of opinion that they were not properly paid at all, but if that view were correct, why should they get on the register? He could not understand why they should get on the register, and yet status by being there. It would certainly be a disadvantage to have a test case tried, and if a case were formed, which he hoped might be the outcome of present discussion, and if they could get up a case, involving all the points which they could combine in it, it would be of great value. They might first before the Master of the Rolls, then to the Appeal Court, and ultimately before the House of Lords, and thus get many of these difficult questions decided.

The secretary said he had no doubt the Council of the Society of Arts would give very careful consideration to any application which might be made with a view to the formation of a committee on this question.

The chairman then proposed a vote of thanks to Mr. Bund for his able paper, and for the impetus which he had given to a movement which it was to be hoped would be of great benefit to the evening. It seemed to be the general opinion that an association or committee should be formed to see in what way the working of the Trade Mark Act could be improved, and how difficulties which had arisen under the existing system could be removed. It would be very satisfactory indeed if such a result should follow from the reading of the

A vote of thanks was carried unanimously, and the meeting terminated.

## GENERAL NOTES.

**Iron and Steel Institute.**—The annual meeting of the Institute will be held on Wednesday, May 4th, and two days, in the hall of the Institution of Civil Engineers. The president elect (Mr. Josiah T. Smith) will deliver the inaugural address on the first day.

**Course on Plumbing.**—A course of six lectures on the Science and Art of Sanitary Plumbing will be given by Mr. J. H. P. Hallyer, at the House of the Society of Arts, on June 1, 14, 28, July 12, 26, at 7.30 p.m. The course will be especially addressed to working plumbers, and will be illustrated by examples, diagrams and working models. Examinations of a practical nature will be held at the close of the course, and two large silver medals and several smaller silver and bronze medals and certificates of proficiency will be awarded by the National Health

**Copyright Bill.**—A meeting of the Law Amendment Society will be held on Monday evening, May 2, at 8 p.m., at 1, Adam-street, Adelphi, when a discussion on the Copyright Bill promoted by the Society, will be opened by Mr. John Westlake, Q.C., LL.D. Lord Reay will take the chair.

**Royal Albert Hall.**—Amongst the arrangements for the season at the Royal Albert Hall, it is announced that eight oratorio concerts will be given, at which Mr. Sims Reeves will sing in oratorio for the last time. The first of these concerts was held on the 27th of April, and the last will be on Saturday morning, the 9th of July. It is stated that at this last-mentioned concert Mr. Sims Reeves will make his last appearance in oratorio.

**Iron Sleepers.**—In this country iron sleepers have only been used experimentally, but in Belgium and Germany they have been employed for a considerable time. In the past two years it is calculated, say Messrs. Bolling and Lowe in their report, that nearly 130,000 tons have been placed on the German railways. In Germany there are many hundred miles of line running through sandy districts, for which the iron sleeper is said to be well suited.

**Blast Furnace Cinder.**—so long regarded as a waste product, is thus treated at the Silesian Iron Works near Liège, Belgium. The molten slag, as it is commonly, though inaccurately called, flows direct from the blast furnace into a stream of cold water, whereby it assumes a finely-divided condition, like coarse sand. It is raised by an elevator, deposited in wagons, and sent away at once, to serve as railway ballast for which purpose it is well suited.

**Artificial Stone.**—In the report on the Exhibition of Applied Science, Paris, 1879 (*Journal* vol. xxviii, p. 164), the articles of artificial stone, by M. Dumesnil, were referred to. This substance is composed as follows:—In 500 litres (110 gals.) of water, are dissolved 7 kilos. (15½ lbs.) of alum, 6 kilos. (13½ lbs.) of slaked lime, and 1 kilo. (2½ lbs.) of yellow ochre, to which is added 1 kilo. of glue dissolved in 5 litres (1 gal.) of hot water. In this mixture, 900 litres (198 gals.) of plaster of paris are tempered, and then half that quantity of fine river sand, free from clay, is added. This preparation, run in moulds, sets in about twelve hours, and acquires great hardness. To protect the building blocks, thus obtained, from the action of rain, it is sufficient to give them three coats of silicate of potash dissolved in water.

**Tobacco in France.**—The following table from a recent report shows that the consumption of tobacco in France has been steadily increasing:—

		Population.	Amount consumed.		Amount per head.
			Kilogrammes.	Grammes.	
1816	....	29,250,000	8,981,403	....	307
1826	....	31,678,853	11,595,084	....	366
1831	....	32,731,256	11,071,088	....	338
1841	....	34,018,716	16,481,934	....	484
1851	....	35,546,919	19,718,089	....	555
1864	....	37,133,424	28,019,803	....	755
1866	....	37,807,203	30,627,663	....	810
1872	....	35,844,414	27,031,000	....	754
1876	....	36,643,087	31,188,848	....	851

The amount consumed in the different departments varies very much. Snuff-taking is most practised in Oise, Seine Inférieure, Eure, and Eure-et-Loir, at the maximum rate of 375 grammes per head; and least in the departments of Doubs, Pyrénées Orientales, Nord, Haut Rhin, and Haute Savoie, where the average is but 100 grammes. In smoking, however, there is rather a reverse order of things, the Nord, Haut-Rhin, and Pas-de-Calais consuming at the rate of two kilogrammes per head, while the minimum is found in Haute Savoie, Cantal, Corrèze, Creuse, Aveyron, Dordogne, Lot, and Lozère. Ten departments only consume tobacco above the average, while 70 are actually below it. If all France smoked the same quantity as do the people of Nord, Haut-Rhin, and Pas-de-Calais, the consumption for the whole country would be 78,286,174 kilogrammes, instead of 31,000,000; and *vice versa* it would be only 8,265,968 kilogrammes if calculated according to the average of Lozère, which is only at the rate of 171 grammes per head.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MAY 4.—“Buying and Selling; its Nature and its Tools.” By Professor BONAMY PRIOR, M.A. Lord ALFRED S. CHURCHILL will preside.

MAY 11.—“The Manufacture of Glass for Decorative Purposes.” By H. J. POWELL (Whitefriars Glass Works). WILLIAM SPOTTISWOODE, LL.D., F.R.S., will preside.

MAY 18.—“The Electrical Railway, and the Transmission of Power by Electricity.” By ALEXANDER SIEMENS. Dr. SIEMENS, F.R.S., will preside.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 10.—“Trade Relations between Great Britain and her Dependencies.” By WILLIAM WESTGARTH.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MAY 12.—“Recent Progress in the Manufacture and Applications of Steel.” By Prof. A. K. HUNTINGTON.

MAY 26.—“Telegraphic Photography.” By SHELFORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

APRIL 29.—“The Building Arts of India.” By General MACLAGAN. ANDREW CASSELL, Member of the Indian Council, will preside.

MAY 13.—“Burmah.” By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B. Sir RUTHERFORD ALCOCK, K.C.B., will preside.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fourth Course will be on “The Art of Lace-making,” by ALAN S. COLE. Four Lectures.

*Syllabus of the Course.*

## LECTURE III.—MAY 2.

Fringes. Twisted thread-work in England in the 15th century. Early designs for plaited and twisted threads. Italian, Flemish, French, and English pillow lace. Laces of primitive design.

## LECTURE IV.—MAY 9.

*Resumé* as to styles of design in hand-made lace. Traditional patterns. Sketch of the development of inventions for knitting and weaving threads to imitate lace. Differences between machine and hand-made laces. Modern hand-made laces at Burano, Bruges, Honiton, &c.

This course will be illustrated by specimens of lace. Diagrams and photographs enlarged will be shown by means of the lantern and oxyhydrogen light.

The Fifth Course will be on “Colour Blindness and its Influence upon Various Industries,” by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

May 16, 23, 30.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 2ND.—SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Alan S. Cole, “The Art of Lace-making.” (Lecture III.)

Farmers' Club, Inns of Court Hotel, Holbo 4 p.m. Mr. T. Duckham, “The Effect of L Owned by Corporate Bodies.”  
Royal Institution, Albemarle-street, W., 2 p.m. Meeting.  
Institute of Surveyors, 12, Great George-str 8 p.m. Mr. G. M. Freeman, “Land Law Re Medical, 11, Chandos-street, W., 8½ p.m. Oration.  
Victoria Institute, 7, Adelphi-terrace, W.C., 8 p W. D. Ground, “An Examination of the I of Mr. Herbert Spencer.”  
Law Amendment Society, 1, Adam-street, Adel 8 p.m. A Discussion on the “Copyright I being promoted by the Society, to be open statement by Dr. John Westlake.

TUESDAY, MAY 3RD.—Royal Institution, Albemarle-st 8 p.m. Prof. Dewar, “The Non-Metallic E (Lecture II.)

Central Chamber of Agriculture (at the Hoc SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, W S.W., 8 p.m. Discussion on Mr. Walter R. Paper, “The Relative Value of Upland Waters in Producing Scour.”

Pathological, 63, Berners-street, Oxford-st 8½ p.m.

Biblical Archaeology, 9, Conduit-street, W., 8 p.m. Ernest de Bunsen, “The date of Menes.” Eisenlohr, “An Historical Inscription.”

Zoological, 11, Hanover-square, W., 8½ p.m. 1. Parker, “Some Points in the Anatomy of t in the Hare and Rabbit.” 2. Prof. F. J. “Contributions to the systematic arrange

*Asteroides*. Part I., “The species of the genus S. Dr. M. Watson, “Additional Observations Anatomy of the Spotted Hyena.” 4. M Thomas, “The Indian species of the genus I

WEDNESDAY, MAY 4TH.—SOCIETY OF ARTS, J Adelphi, W.C., 8 p.m. Prof. Bonamy Prior and Selling; its Nature and its Tools.”  
Iron and Steel Institute, 25, Great George-st 10½ a.m., General Meeting of Members. The Elect (Josiah T. Smith, Esq.) will deliver hi Address. A Selection of Papers will be re cussed.

Entomological, 11, Chandos-street, W., 7 p.m. Archaeological Institute, 16, New Burlington- 4½ p.m. Annual General Meeting.

Obstetrical, 63, Berners-street, Oxford-street,

THURSDAY, MAY 5TH.—Royal, Burlington-house, W., 4 Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. F Balfour, “The Dragon's Blood Tree and its 2. Prof. G. Busk, “New Species of *Clept Challenger Expedition.”* 3. Prof. Bayley Hal

Genera of Plants from Madagascar.”  
Chemical, Burlington-house, W., 8 p.m. 1

The Election of Fellows. 2. Mr. E. W. Fr Action of Humic Acid on Atmospheric Nit

Mr. R. T. Flimpton, “The Active and Iner mines.” 4. Mr. L. D. Thorne, “The Prod Action of Alkalies on Ethyl G. Ethylacetate

5. Mr. T. Purdie, “The Action of Sodium on Fumaric Ether.”

South London Photographic (at the Hoc SOCIETY OF ARTS), 8 p.m.

Royal Institution, Albemarle-street, W., 3 Tyndall, “Paramagnetism and Diamagnetis ture II.)

Iron and Steel Institute, 25, Great George-st 10 a.m. Reading and Discussion of Papers

Civil and Mechanical Engineers, 7, Westminster S.W., 7 p.m. Annual Meeting.

FRIDAY, MAY 6TH.—Royal United Service Institute, yard, 8 p.m. Captain J. T. Bucknill, “The of Buildings from Lightning.”

Royal Institution, Albemarle-street, W., 8 p.m. Meeting. 9 p.m. The Hon. George Brod Land Systems of England and of Ireland.”

Geologists' Association, University College, W. Philological, University College, W.C., 8 p.m. Martineau, “The Rhetoric-Romance Dialect.”

Iron and Steel Institute, 25, Great George-st 10 a.m. Reading and Discussion of Papers and concluded.

Quekett Microscopical Club, University Coll 8 p.m.

National Health Society, 23, Hertford-street, (Drawing-room Lectures.) Mr. C. N.

“Sanitary Relations of Local Self-Governm

SATURDAY, MAY 7TH.—Royal Institution, Albemarle- 3 p.m. Prof. Henry Morley, “Scottish English Literature.” (Part II.)

## JOURNAL OF THE SOCIETY OF ARTS.

No. 1,485. Vol. XXIX.

FRIDAY, MAY 6, 1881.

*Communications for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W. O.*

## NOTICES.

## CANTOR LECTURES.

Third lecture of the fourth Course on "The lace-making" was delivered by ALAN S. Monday, 2nd inst. Attention was drawn to gradual growth of design, as exhibited in the Italian, Flemish, French, and English lace, and the distinctive characteristics of Brussels, and Valenciennes lace were noted. A series of specimens of lace were shown, and enlarged photographs of representative pieces were shown by means of the aid of oxy-hydrogen light.

## ART FURNITURE EXHIBITION.

Preparations for the Exhibition of Works of Art in Furniture at the Royal Albert Hall are being proceeded with, and it is expected the Exhibition will be opened on Thursday, May 11, at the same time as the General Art Exhibition at the Albert Hall.

## MEETINGS OF THE SOCIETY.

## PHYSICS AND CHEMISTRY SECTION.

Meeting, April 28, 1881; ALLEN THOMPSON, F.R.S., in the chair.  
Paper read was on—

## IMPURITIES IN WATER, AND THEIR INFLUENCE UPON ITS DOMESTIC UTILITY.

By George Stillingfleet Johnson, M.B.C.S., F.C.S.

There are some impurities found in the water of our country, especially in those rivers which, like the Thames, pass through the immediate neighbourhood of this building. I shall have little to say this evening of their course through large towns, or of the impurities which I allude to organic impurities, the effluvia of living beings, sewage, and the like, and I shall for keeping silence upon this great

subject is the incompleteness of our knowledge regarding it. Our highest medical authorities seem to be at variance as to the nature and degree of the baneful influence exerted by those impurities which I have mentioned upon the human economy, with the exception of the so-called specific poisonous products of such diseases as typhoid and cholera; and our highest chemical authorities are very much at variance as to the best method of estimating or determining the amount of these organic pollutions in waters, as they also are in the various accounts they give of the processes by which nature removes them. It would ill become me, therefore, to do more than hint at the existence of this source of contamination of water, unless I stood prepared to bring forward some new facts or experiments throwing light upon the subject, which I am not in a position to do. I must, therefore, confine myself this evening to the discussion of some of the more important inorganic impurities contained in natural waters, and their influence upon the domestic utility of the important liquid which contains them.

The word "impurities" has occurred several times already in this paper. I have also spoken of "pollutions" and "contaminations," all of which expressions tend to convey the idea that the presence of substances so described, in the water we drink and employ for household purposes generally, must needs be injurious and prejudicial. Now, the tendency of this paper will rather be to show the great usefulness of many of these so-called "impurities" in natural waters; and the word is used here in its strictly chemical sense, to indicate anything which we find in and accompanying water which is not the chemical compound,  $H_2O$ .

Pure water, the compound containing two atoms of hydrogen combined with one atom of oxygen, is a pure chemical substance which is never found in nature. We explain this by the statement that water exerts a solvent action upon various gases and solids.

It is, then, by virtue of its solvent action that water becomes impregnated with the impurities of which I am to speak; and I will, therefore, ask you to follow me while I make a few preliminary remarks upon, and show you a few experiments illustrating, the nature of solution. The process of solution consists essentially in a change of physical state, without alteration of chemical constitution. Thus, when sugar or common salt is dissolved in water, we can obtain the solid sugar or chloride of sodium by simply evaporating the water; and these are instances of true solution; but, if metallic copper be dissolved in nitric acid, that is an instance of solution accompanied by chemical change; for, if we evaporate the blue liquid thus obtained, we have a deposition, not of metallic copper, but of nitrate of copper, the salt formed by the chemical action which takes place between that metal and nitric acid. Solution proper, then, consists in a change of physical state simply without change of chemical constitution. Now, we know of but three physical states in which matter can exist, the solid, the liquid, and gaseous. The solvent or substance which brings other substances into solution is usually a liquid. The dissolved body may be either a solid or a gas.

Now, the physical state in which we find any

substance depends to a great extent upon the nature and intensity of the physical forces which happen to be acting upon it at the time. Besides the action of solvents, the two physical forces, heat and pressure, exert a powerful influence upon the physical state of matter. The essential difference between the three physical states of matter is one of the relative freedom of motion which exists between the molecules or ultimate particles of which the matter consists, the gaseous form of matter possessing the greatest, whilst the solid possesses the smallest, degree of molecular mobility. Heat, on the one hand, increases this mobility of the molecules of matter, whilst pressure has the reverse effect.

Next, observe that the solvent (liquid water, *e.g.*) is in the intermediate condition, as regards molecular mobility, between the solid and the gas, whose physical state it must assimilate with its own before it can bring them into solution. It follows, then, that the liquid solvent must bind a gas in chains, as it were, must diminish the free mobility which exists among the particles of that most elastic form of matter, whilst it will have to increase the molecular mobility of the comparatively sluggish solid, in order to make them respectively assume its own physical state. Accordingly, we should expect to find that a liquid will have its solvent action upon solids increased by the application of heat, whilst its power of dissolving gases will be diminished by heat, but improved by pressure. And these laws are obeyed in almost all instances.

I will now show you one or two experiments, to illustrate these preliminary remarks upon solution. When I stir up these two white powders in separate beakers of hot distilled water, you observe that one of them (which is powdered sugar) becomes readily incorporated with the water, changes its physical state, assuming that of its solvent, is dissolved. That is an instance of a soluble substance. This other powder, however, refuses to do anything but remain partially suspended in the water, making the liquid look milky, whilst the greater part of it (for it is very heavy) sinks and remains at the bottom of the beaker. It is the salt called sulphate of baryta, and is one of the most insoluble bodies known.

To illustrate the effect of heat in assisting the solution of a soluble solid substance in a liquid, it will be sufficient to cool this hot saturated solution of iodide of lead, when we find that water, which was capable of retaining a large quantity of that salt in the liquid state whilst hot, becomes incapable of doing so as it cools, and the excess of salt separates out from the solution in the crystalline form.

To demonstrate the action of heat in retarding the solution of a gas in a liquid, I will first pass up a little water into this tube (which contains dry ammonia gas confined over mercury). As soon as the water reaches the gas, you see that the latter disappears, being dissolved by the water. Now, if I pour a little hot water over the outside of the tube, we shall soon see the effect of heat in increasing the molecular mobility of the ammonia, for the restraining power of the water, at this high temperature, becomes insufficient to control the elasticity of its volatile companion, and the ammonia bursts its chain and resumes the gaseous condition. As the tube cools again,

the solvent power of the water is again tried and the gas disappears. Not only does temperature of the liquid solvent exert influence upon the quantity and quality of substances which it is capable of dissolving; solvent action of a liquid is often considerably modified by the presence therein of substances which it has already dissolved.

We will consider this influence of dissolved matter in water upon its solvent action on other forms of matter somewhat fully, since it is to explain the presence of some of the impurities found in waters; and it will be convenient to divide the subject into two parts, *viz.* :—

1. The influence of dissolved gases upon the solubility of solids.

2. The influence of dissolved solids upon the solubility of other solids.

1. Excluding those cases in which a chemical action occurs, resulting in the production of an insoluble compound by the action of a dissolved gas upon one or the other of the elements in a dissolved solid, the general tendency of dissolved gas is to increase the solubility of their common solvent. As an illustration I will cover this solution of copper sulphate with a strong solution of ammonia gas in water, and see now three layers in the containing beaker. Below the blue solution of copper sulphate is the colourless solution of ammonia gas in water, and between the two, a light blue turbidity of which is due to the presence of suspended hydrated oxide of copper, a substance which is insoluble in pure water, and in neutral and alkaline solutions, but which is soluble in a solution of ammonia gas in water, a dark blue liquid, which you see is formed when I stir up the contents of the beaker. There are other instances which will occur to every chemist of solid bodies quite insoluble in pure water to the solvent action of a solution of ammonia gas in water. It appears, then, that the dissolved gas confers a degree of molecular mobility upon the solid which has dissolved it, or at least enables the water to produce the requisite freedom of motion amongst the molecules of an otherwise solid, which is necessary in order to compare the solid with the liquid state.

2. It is frequently observed, and is well known amongst the halogen group of elements, that an insoluble salt is rendered soluble by the presence of its common solvent of a very soluble body. One of the most striking and common examples of this is seen in the case of the curc iodide, which is entirely insoluble in water, but is readily dissolved by water containing a solution of potassium iodide—a very soluble salt. It is essential that the potassium iodide be present in a somewhat concentrated solution, for, as you see in this beaker, when a solution of mercuric iodide is mixed with a large quantity of pure water, the red mercuric iodide separates out. If there be any chemical action between the iodides in this case, it is of the very feeble kind. Indeed, some experiments of my colleague, J. M. Thomson, have tended to show that the double salts formed by dissolving insoluble compounds in soluble ones are compounds, all, they are molecular, not atomic combinations.

it all events, interesting to remark, that dissolved solid assists the solution of another solid, it is the more soluble substance—that is endowed with freest molecular mobility—serves to bring about the liquefaction of the luggish solid; and there are instances of action which cannot be at all explained by action, as in the case of the solubility of lime in a strong solution of sugar.

metimes happens that the action of a solvent is aided, by the formation of a protecting film of a soluble substance upon the surface of an insoluble solid. Thus, marble, which is a compact lime variety of carbonate of lime, is freely dissolved by a solution of hydrochloric acid gas in the only solid product of the accompanying action being the salt known as calcic chloride. Now, calcic chloride is freely dissolved in water, and, as each particle of it is formed on the surface of the marble, it is dissolved off by the action of fresh surfaces of marble are constantly

to the action of the hydrochloric acid. we immerse marble in water containing hydrochloric acid and sulphuric acid in solution, the surface speedily becomes covered with an insoluble film of calcic sulphate, and the action of the acid on the marble is still there in abundance; hydrochloric acid is also present in quantity, adequate for its solution; but, by reason of the insoluble film of calcic sulphate, they are prevented from acting upon one another. chemical force can only act at infinitesimally small distances." Another instance of the protection of an insoluble film upon the surface of a otherwise soluble solid is seen in the case of iron and ferrous sulphide. When this substance is immersed in sulphuric acid, the salt known as ferrous sulphate is produced. Now, green vitriol, or ferrous sulphate, does not dissolve in cold, strong sulphuric acid, but it dissolves readily in hot dilute sulphuric acid. When, therefore, I pour cold oil over this ferrous sulphide, there is little action, a film of ferrous sulphate forming on the surface of the sulphide, and protecting the surface beneath from the action of the acid; but if I pour water into the containing vessel, a reaction is at once set up, heat being developed, and an admixture of the water with the acid, cold sulphuric acid being converted into hot sulphuric acid, which dissolves off the ferrous sulphide as fast as it is formed.

we now pass on to a consideration of some of the impurities contained in natural waters—in water supplied to us for use in every-day life—impurities, where that is possible, the sources and of contamination, and, further, discussing the precautions necessary for the removal of impurities as are prejudicial to the domestic use of this valuable agent. First, then, we will consider the gas found in solution in natural waters, with the trifling exceptions, viz., some of the rarer natural waters, the gases dissolved in water are which are present in our atmosphere—oxygen, nitrogen, carbonic acid, and ammonia. oxygen and nitrogen gases, the elementary constituents of the atmosphere, are present in appreciable quantities, and are far less soluble than the other two.

carbonic acid and ammonia, or compound gases, are chiefly products of animal life, and are

constantly being removed by plants and vegetable organisms, but they are also more soluble in water than the first two. The carbonic acid is present in larger proportion than the ammonia, whilst it is also far less soluble than the latter gas. Indeed, after a long continued fall of rain, the presence of ammonia in the air of a place is hardly recognisable.

Spring-waters are very apt to contain much larger quantities of  $\text{CO}_2$  than rain-water or river water. Meandering, as they frequently do, through subterranean passages, they are exposed in their course to influences peculiarly favourable to their conversion into strong solutions of this gas. The earth being the common receptacle for dead organic matter, and her cavities being in many cases never penetrated by the sun's rays, or ventilated in any way, accumulations of carbonic acid are to be expected in these regions. The water, then, which is often very cold (it may be produced by melted snows), is churned up at frequent intervals along its course with these terrestrial gases, and becomes, in consequence, highly charged with them.

We are able to demonstrate the presence of dissolved gases in water, by simply boiling it in an apparatus such as this which I now show you, and collecting the permanent gas which escapes, as is being done here. The presence of these dissolved gases in water appears to be in every way beneficial. If we consider water as a beverage, the sparkling and refreshing effect of spring-water is largely due to the dissolved gas, especially to the carbonic acid gas which it contains. Again, boiled or distilled water, from which the gases have been expelled by heat, is unwholesome and insipid, but may be again rendered palatable by aerating it with charcoal. But more than this, absolutely gas-free water (which, however, can only be obtained by boiling water in vacuo), boils at a temperature considerably above  $100^\circ\text{C}$ ., and with violent explosion.

Again, it is probable that the oxygen dissolved in water oxidises, and removes some of the more readily putrescible organic matters contained therein; and it certainly is of the utmost importance to the life of fish. The dissolved gases in water also exert an important influence upon its solvent action for solids, as we shall now find. The solid substances dissolved in waters are generally chlorides, sulphates and, carbonates of the alkalies, and of the alkaline earth metals.

Those waters which contain the alkaline earths in solution, are divided into (1) calcareous and (2) magnesian waters, the former containing sulphate or carbonate of lime in solution, the latter sulphate or carbonate of magnesia. Such waters are said to be hard. Now, it is in the case of the carbonated calcareous and magnesian waters that we observe most distinctly the influence which a dissolved gas may exert in modifying the solubility of a solid in their common solvent. For the carbonates of lime and magnesia are insoluble in pure water, or nearly so; but considerable quantities of these salts may be brought into solution by water charged with carbonic acid gas. For instance, if I bubble carbonic acid gas through this clear lime-water, we first observe a milkiness, due to formation of the insoluble carbonate of lime; and on continuing to pass the gas, we finally obtain a clear solution. The dissolved

gas enables the water to overcome the molecular sluggishness of the calcic carbonate, and to reduce it to the liquid condition; just as the dissolved ammonia gas in our previous experiment enabled the water to hold in solution the hydrated cupric oxide. Now, if I boil this clear solution of bicarbonate of lime, the excess of gas is expelled by the heat (just as the ammonia gas was expelled from its dissolving water when the temperature of the tube containing the solution was raised), and the water, no longer aided by the mobile carbonic acid gas, loses its power of keeping the calcic carbonate in the liquid state; accordingly that salt is reprecipitated.

Bearing the facts in mind, we shall be able to explain some of the phenomena of nature in connection with this subject of calcareous waters. We have seen that spring-waters are frequently highly charged with carbonic acid gas; now carbonate of lime, in the shape of chalk deposits and limestones of various kinds, is a very constant ingredient of the soil in many parts of the earth's surface. It must, therefore, be a matter of very frequent occurrence for water, already highly charged with carbonic acid gas, to come in contact with carbonate of lime in the course of its subterranean wanderings; hence the frequent contamination of natural waters with dissolved carbonate of lime. But there is another interesting and very beautiful phenomenon which we are enabled to explain by the light of the above facts. I mean the formation of stalactites and formations such as are figured in the diagram on the wall. Suppose a water holding in solution much carbonate of lime and carbonic acid gas to trickle slowly through the roof of a cave. From each drop of water, as soon as it finds itself exposed to the common air, some of its dissolved carbonic acid gas will begin to evaporate, and for each molecule of gas which thus leaves the water, a molecule of calcic carbonate will be deposited in the solid form. Let a few of these solid particles adhere to the roof of the cavern, and from the nucleus thus formed, the production of vast conical masses, such as are here portrayed with their beautiful tapering apices pointing towards the earth, is only a matter of time. The nature and quantity of the dissolved salts in spring water will, of course, vary with the composition of the soil through which it has passed. Many mineral waters are of great medicinal value.

We will next consider the influence of dissolved lime-salts upon the domestic utility of water. Is "hardness" in water prejudicial? If we consider the water as a beverage, the answer would be, No. The worst that hard waters have been accused of is that they produce a tendency to calculous formations in those who drink them. But I think the water-drinker may answer to that charge, "Not proven." And, on the other hand, we cannot but remember that the metals calcium and magnesium, in combination with phosphoric and carbonic acids, play the important part of conferring the requisite degree of hardness and stability to our frame—are, in fact, the earthy constituents of the skeleton. But there is another purpose for which water is employed, viz., for washing, and which is hardly less important than that we have just considered. For this purpose hard water is certainly disadvantageous.

Soap contains fatty acids, which form compounds with the lime and magnesia waters, and no lather will be produced till lime and magnesia dissolved in the water be precipitated in this way. And this occurs with a waste of soap.

Now, what is called the temporary hardness of water may be removed by boiling it. The action of the dissolved carbonic acid gas, which means, leads to the removal of the calcic carbonate from solution in the water, and the hard to that cause is then removed. But the water may contain sulphate of lime in solution, which cannot be removed by boiling the water. On the other hand, unless the water had been previously saturated with the salt, the evolution of steam in boiling rather tends to concentrate its solution, and permanent hardness due to this cause would be increased. Moreover, there is a further objection to the use of water (except in small quantities) for the purpose of removing its hardness, since, besides the action of fuel which is necessarily incurred, the deposition of calcic carbonate tends to form incrustations, often of considerable thickness on the walls of the vessel employed for the purpose, and if they do not lead, as they have done, to dangerous accidents by their becoming detached, and producing explosions of steam, by allowing the water to come in contact with the strongly heated metal wall of the boiler, yet must invariably cause great waste of fuel owing to their inferiority as conductors. Therefore, the process of Mr. Clark, which is conducted without any application of heat, is a great boon to mankind, especially as it offers the additional advantage of clarifying a water as effectively as any filter.

The problem before us is essentially this: How may dissolved calcic (and magnesian) carbonates be best removed from solution in water? Or, may these salts be converted into some soluble form? Or, may these salts be converted into some insoluble matter with the smallest possible expenditure of time and money? We have seen that the method of boiling the water, though objectionable on the score of expense, and liable to accidents, &c. Now, in Mr. Clark's process, I have said is preferable, the suspended calcic carbonate produced has to be removed by subsidence. There are two methods by which suspended matter is removed from water, viz., subsidence and filtration, and these processes are also adopted by man for the same purpose. It is claimed for the method of purification that organic matters are oxidized by the substances employed, e.g., charcoal, which has the property of retaining oxygen gas in its pores. In the process of Mr. Clark also undoubtedly dissolved organic matters from waters, which is added acting as a mordant, and their precipitation. Mr. Clark's process is as follows:—By adding quick lime or hydrated lime to a carbonated calcareous water, the carbonic acid gas, which is holding the carbonate in solution, is first removed by combination with the added lime, and the carbonate of lime thus produced falls, together with that precipitated by the lime, as a solid insoluble precipitate. The turbid water is left to clear by subsidence, and afterwards drawn off freed from its hardness.

we hitherto been speaking of what may be unavoidable impurities in water—impurities, viz., which are introduced by natural causes which are beyond the control of man; before concluding, I must allude, however, to a very important accidental source of contamination of water, which is sometimes introduced by man himself, I mean the contamination with lead. And here we shall find that cause of dissolved matters in any water is very important in modifying its solvent action upon this metal. Lead, from the ease with which it is worked, and the resistance it offers to atmospheric action, changes of temperature, &c., has been found to be a convenient metal wherewith to construct for the conveyance of water, and cisterns for storage. But lead is dissolved in considerable quantities by some natural waters. A long-continued ingestion of that metal, even in very minute quantities, produces serious symptoms of disease in the human system so much so that the metal has given its name to at least two specific affections, lead colic and palsy. It becomes, then, a matter of the greatest importance to be able to state, from a knowledge of the ingredients of any given water, whether or not it will be safe for persons to drink it after it has been stored in leaden cisterns—whether or not that particular water is able to exert any solvent action upon the metal. We are able, in many cases, to do. For it is found that pure water, free from dissolved solids and gases, has no solvent action on lead. But water containing dissolved matters becomes impregnated with lead, oxide of lead, to a certain extent, soluble in

**Practical Deduction:**—Rain-water, stored in cisterns, is not to be used for drinking purposes. When waters containing carbonates, and sulphates, in solution are stored in cisterns, the metal becomes coated with an insoluble protecting film of carbonate of lead, further action being prevented, and the water does not become impure.

**Practical Deduction:**—Carbonated and sulphureous waters may usually be stored in cisterns in impunity. The film which forms on the surface of the metal should by no means be removed.

Waters containing nitrates and chlorides in solution cannot safely be stored in leaden cisterns, since the nitrate and chloride of lead are soluble. The practical deduction from this is

cluding, I hope I have convinced most of you that, though we do not drink pure water, it would be very much worse for us if we did that, whilst we may sometimes be inclined to say, "Why is such a substance here?" we find at last that it serves some important purpose which had escaped our ken—in fact, that it naturally led to wonder at the Wisdom which has made so rough intricate and complicated labyrinths of the water supply, and are forced to see the ultimate tendency and result of even the most striking anomalies as the "impurities in

## DISCUSSION.

The Chairman said, as his chemistry was of a very ancient date, he should not venture, in any remarks he might be bold enough to make, to discuss the chemical part of the subject. He had been exceedingly gratified by the lucid exposition of that part of the extensive subject which Mr. Johnson had selected, as well as by the well-devised experiments which had been performed, and which had brought out so fully the illustration of the principles laid before them. It was quite necessary to avoid, in a paper such as this, entering upon the extremely extensive and difficult part of the subject involved in the consideration of the organic impurities of water, as that could only satisfactorily be dealt with in a separate paper. A great part of his life had been divided between two residences, in which very opposite extremes in the condition of water existed, so that he had had an opportunity of observing, in a general way, the effects of these conditions. At Aberdeen he used the water of the Dee, which approached almost to distilled water, with the exception of course of the gases, and in Glasgow the water of Loch Katrine, which, was equally pure with the water of the Dee, and in both instances he was made aware of the circumstances which Mr. Johnson had so well explained with reference to the disadvantage that might arise from the purest water, more especially from the solution of the leaden pipes through which the water passed, or from the cistern in which it was kept. The introduction of slate cisterns must be considered a very great advantage, as they protected one against the risk, which might occur from keeping water for a long time in leaden cisterns. With respect to pipes, he was quite aware of the evil when they were new; and if the cistern was of slate, it was only necessary that the water should be run through the pipe a short time, in order to escape the danger which might arise from the water remaining a considerable time in the leaden pipes. He had known an instance of lead colic being produced simply from inattention to this precaution. He had also had ample experience of the process for softening water, for it so happened that the water supplied to the house in which he lived near Edinburgh was the hardest with which Professor Clark had ever come in contact. Few were aware of the evils belonging to extreme hardness of water. The water to which he referred, when used for boiling meat, had the effect of making it quite red; vegetables shrivelled up in a most wonderful way under its influence, kettles became encrusted, tea could not be made, and washing with it was quite out of the question. For the cure of this, by Dr. Clark's direction, he added a ninth part of lime water to the ordinary water, and during the night a subsidence, not only of the whole of the carbonate of lime, but of all the impurities took place, the water being then fit for domestic use. Those present must have been convinced by the author of the advantages which should belong to such impurities when occurring in a moderate degree, though they might not go to the length which the well-known old lady of St. Andrew's did, who, when great efforts had been made to introduce new water in the place of one which had not been favourably looked upon by the inhabitants before, said that she did not think much of the new water, as it had neither taste nor smell.

Mr. Lovegrove had been told that in nine cases out of ten water was contaminated in zinc cisterns, and it would be interesting to know the effect of water contaminated with zinc. A great deal had been said as to the impurity of water in daily use, and, therefore, he should like to know whether, supposing water passed through say 100 miles of iron pipes, the oxidation of the pipes would tend to improve or deteriorate the quality of the water.

Mr. Maignen said it was pleasant to find there was no great fear of mineral impurities in water doing much harm to the health of people. The germs of organic impurities caused disease, but lime did not do so except when in excess. The question of softening water was somewhat a cumbersome matter, and it might be egotism for him to speak upon the subject, as he had ventured to introduce a process to remove many impurities from water. The object of the process was to impregnate charcoal with lime, so that when the water was filtered through the charcoal, the lime in the charcoal took up the bicarbonate of lime in the hard water to a certain extent. This process could be carried on by filtration, and, through the kindness of Mr. Johnson, he had been allowed to put upon the table specimens of the filtering medium, and filters which he had patented. In the inside of the filter was a cone, the outside being covered with an asbestos bag, and charcoal being put into the water; upon its filtering, the bag became thinly coated with charcoal, which acted as an efficient filter.

Mr. Clements said that having paid some attention to the subject of impurities in water for the last few years, he found there had been many cases of disease caused by water from sewers passing through the soil into wells; and some time ago he heard of a case which occurred at Croydon, where a man had been killed by drinking this impure water. There appeared to be a considerable discrepancy in the opinion of various persons as to finding out whether water was pure or not; and, some time ago, a gentleman in the South of London sank a well to obtain water, and having procured what appeared to be clear water, he gave some to him (Mr. Clements), and, upon testing it, he found it was very bad, as compared with the water supplied by the Kent and London companies. A great deal of discussion had taken place upon the subject of impurities in water lately, and much difference of opinion existed upon the matter.

Mr. Johnson, in reply, said that as regards contamination of water with zinc, he had no experience. He spoke with some diffidence upon such a subject, seeing so many distinguished medical men present, but from what he knew he did not think that zinc was a dangerous metal, it being frequently administered medicinally, nor could he say what action water containing impurities had upon zinc. As to water passing through a long iron pipe, there was no doubt the water would have a very considerable action upon the metal. The pipe would become corroded, and the water at the point of exit would be turbid, more especially with ferric oxide. He could not say, in an off-hand kind of way, that impurities in water were always beneficial, because, in considering the question of whether water would act upon any metal, it was not sufficient to say that the water was impure. We must always consider what the nature of the impurities is. Water which was impure with carbonates and sulphates was safe to store in lead, but, on the other hand, water full of nitrates and chlorides would be exceedingly dangerous to store in lead. As regards the action of the carbo-calcis filter referred to by Mr. Maignen, no doubt it was a very good plan for the rapid filtration of small quantities of water, but the great advantage of Clarke's process was seen when enormous quantities of water were required; for instance, in the case of large institutions, where soft water was necessary. As to the organic impurities in water, he had left that out of consideration altogether. He was quite aware that the commencement of his paper was somewhat elementary, but it was impossible to avoid introducing some elementary facts, and he thanked those who possessed knowledge upon the subject for having had patience with him while he touched upon those details.

A vote of thanks to the lecturer having been pro-

posed by the Chairman, it was carried unanimously and the meeting adjourned.

## INDIAN SECTION.

Friday, April 29, 1881; ANDREW C. Member of the Council, in the chair.

The paper read was on—

### THE BUILDING ARTS OF INDIA By General MacLagan, R.E.

Everyone who has been in India has had an opportunity, at some time or other, of noticing of the buildings in the places where he has had to take up his own abode for himself. He may, indeed, be often in places where not much to be seen. The ordinary dwellings of the people will not in India, more than elsewhere, present much that will be thought worthy of notice. Yet, even in the simplest of dwellings, we can see how much can be made of very slender resources, and how well, under the guidance of ancient custom and personal experience, turned to account.

When you hear of cottage walls made of mud, the word does not sound nice to English ears, but when you see them, you find they are stronger and better than you thought. Put together so thickly, the mud becomes one mass that, as it dries, and, hardening as it dries, it forms a corruscating effective protection against heat and against cold. In greater mass, this simple material forms very efficient defensive works of what is known as mud forts in India.

How simply, also, do we find roof covering supplied by a skillful use of the common grass that grow in the jungle (jungle grass, as observed, is the familiar name both for all uncultivated waste, which, except in tracts, commonly becomes a wilderness of thorny trees and tall grasses). A ring of reeds, of no great thickness, does afford much protection against the sun, and not exclude the heaviest rain; but it is wonderful to see what it can do. At places, hills, you shall see local material of ancient origin turned to account for roof covering, in a simple and effective way; large flat slabs of granite stone, doing duty as slates, with lumps of wood upon them to hold them in their place. As in most other countries, there is something worth noticing in the way in which the most of available means and materials are turned to account in very simple ways.

In India, we notice next something more than we get above the very lowest and poorest human habitations, we begin to see marks of demand for some ornament. The ornamentation is of a very rude character, but the demand is wanted more than that the ornament shall serve its direct and essential purpose. Something is wanted more than that the ornament shall find ornamentation given in colour or carving. The white-washed door jambs are streaked with streaks of ochre, diversified with curved spots, and sometimes more ambitious efforts of the owner or the village artist. But there is a demand of a higher class in the rough carvings of lintels and the door-posts of houses in the

ending villages. Rough carvings, no doubt, often are, of simple waving lines or geometric patterns, after the fashion of greater and elaborate work in large cities. They are asymmetrical, perhaps, and very uneven. It is nothing; the eye does not care to be looking at these things. The ideas and are good, if the execution is sometimes rustic. Or not, the effect is very pleasing. It admits of variety of treatment, and the treatment rises to various degrees of excellence. But the great thing is that it is the expression of a felt desire for something more than mere needs. A something pleasing to the eye has become a need, and it finds, in its way, on the spot, the art that is capable of meeting the demand.

A perfectly similar application of this art of carving for external ornament is seen in the hulls of most of the Indian rivers. In many of the boats, of which there are numerous varieties for various purposes, or for general traffic, there is a little deck at the stern, which gives the steersman a raised look-out, and command of the rudder. The deck is also the roof of the little shelter of the cabin and the cooking place. The weathering of the hull which edges this bit of deck on the side of the open body of the boat, presents a concave surface to be ornamented with this wood-work.

A real pleasure to people who have to travel on the river boats, is this rude attempt at simple ornamentation. The crossing of an Indian river, in the middle of a morning march, though sometimes a tiresome and troublesome business, is oftener a refreshing little break in the day's journey when there is no unusual pressure, and when they are in their normal, undisturbed state. You have stepped on board, and your horse is persuaded to follow, you sit down to enjoy a quiet rest as you cross the steady, placid water. No sound meets the ear but the long splash of the big oars, the young day is fresh and cool, the low sun glances on the smooth water. It is peaceful and pleasant; and to all the quietness of the moment, it is something added to this well-purposed effort of humble art—a rough and hard-working, uncultivated ornament. It is the sign of a love for something pretty at—of a care for something more than is required for the mere practical purposes of a safe and substantial ferry boat.

Look with some satisfaction on these lowly, unassuming examples of unaided and unspoiled art. Work of this kind, of all various degrees of higher merit, in point both of construction and ornamentation, will be found in the walls of private dwellings and shop fronts, in the verandah posts, latticed windows, and balconies, in the villages and towns, and among the rude hill tribes, within and beyond the frontier. But we take our view of the art generally from works of a more permanent character. We attach a higher value, in respects, to those that have stood the test of time; that is, we look to buildings erected of our day, some of them very long ago.

It is often a sort of idea that one must go to the great way for specimens of excellence in art, and, among these, the arts connected with building. In India, as elsewhere, people are in the habit of saying that no such

buildings are erected now, as in the days gone by, and that certain old arts are lost. It has been concluded that the capacity for such work has died out. It is one phase of the idea prevailing in all ages that former times were better. It may be the case that we cannot point to anything in India, built within the last hundred years, to equal the grand Hindu temples of Tanjore, the Jain buildings at Abú, the Taj Mahal at Agra, the Jama Masjid at Delhi. The occasion for erecting such buildings, and the means, are wanting. We are not warranted in adding, also, the ability to design and to execute them. It is almost needless to say that for great and beautiful buildings, great expenditure of money and labour is required. It was perhaps a stern necessity that stopped the second tower alongside the stately Kutb Minár at Delhi, and the second tomb opposite the Taj, and elsewhere left intended works unfinished. The ability was not wanting, but the means.

A wealthy prince, happily gifted with large ideas as well as despotic power, orders a work which shall be "exceeding magnificent," and it is done. The skill to plan, and the skill to execute, find full scope for all their highest ambitions. Materials are supplied without stint, of whatever kinds may be required, any number of labouring hands are collected from all quarters to order, and there is little question about cost. The will is there, and the command, and the means, and there is no hindrance. These are happy conditions for the execution of splendid works. If the work was to be a building of stately dimensions, of costly materials, and substantial construction, there you have it. For the master mind to devise and direct the whole was found with the occasion. Given the same conditions now, could India produce such works? Doubtless it could, though the master minds, of the class required, would perhaps be cramped in these days by unwholesome influences.

But besides the men, you must have suitable means to do anything really effective as well as lasting. Nothing great in building, or perhaps anything else, can be done cheaply. We remember Molière's niggardly old gentleman who wants to give an entertainment, but does not like the expense. "Can you give a good dinner for ten guests (or say eight, for what is enough for eight will do for ten)?" "Certainly," replies the chef, who knows him well, "if you give money enough." "There, now," says the miser's obsequious friend, who is helping to make the arrangements, "was there ever a more absurd reply? A good dinner with plenty of money! Why anybody can do that. The clever man is one who can give a first-rate dinner that costs very little." Now this is a kind of thing that has sometimes been attempted with bricks and mortar; and with no better result than was to be looked for in Mons. Harpagon's dinner. If you try to make a cheap building that shall imitate a costly one, you need not be surprised if it turns out unsatisfactory, or something worse. Is anything of this kind done now-a-days by the English folks in India? Many an engineer has unhappy experiences in this way. With the money that can be granted for a certain work—and quite truly it may sometimes be impossible to add to it—he is to carry out something

which, done as it should be done, needs more; so he has to do it as it should not be done. "His poverty, but not his will, consents." And it is the ungracious task of those over him to aid in paring down what he would like to do. It really sometimes cannot be helped. The purpose is served, at least for a reasonable time. And, in that it has been served in the cheaper way, there is, so far, a ground of satisfaction. Only do not let us think that, as a piece of work, it is what it really is not. With supply of adequate means, very respectable work, to state it quietly, has been done by the English in India. Bombay has no need to be ashamed of being the place that has to receive most strangers on their first arrival. They are not made to lose, on coming ashore, the impression made on them when they steam into the beautiful bay.

If not many fine native buildings, either Hindu or Muhammadan, have been erected in our time in India, this may not mean anything more than that the occasions for erecting such buildings are rare, and the resources that can be devoted to them. But it may also, unfortunately, mean that the will of the person for whom the work is to be done has been exerted neither wisely nor well. Within recent years, the combined wealth and zeal of a prosperous Hindu banker have raised, at Mathra, a temple of no small pretension, which at least shows some capacity in the designer. The additions which some of the native princes have made to the buildings at their capitals have not been altogether unsuccessful, though it must be admitted that they have often allowed taste to be violated by the admission of extraneous art. There are, undoubtedly, evil influences of this kind at work, on many other arts and manufactures in India besides those belonging to building.

We might often be inclined to believe that native building power has gone out in other countries where it might be expected to live. Greece, nurtured by the traditions of the past, and taught by its visible inheritances still preserved to her, has done little in modern times to maintain her ancient reputation—very little, if her royal palace is to be an evidence of what she can do. Parthenons are not built now-a-days. We tried it, to be sure, some years ago, in Edinburgh. The money was only enough to build a dozen big pillars. And there they stand, on their proud and airy eminence. And among them, for many a winter and spring, have whistled the raw east winds from the Firth of Forth, which have long ago chilled down all the fervid enthusiasm for a great national monument in purest Attic art. But with plenty of money it would have been done; and with only a claim to good work, which it is, not to high power or originality. We are not looking for originality in India, any more than elsewhere, but for a right use of the art which has existed in days past. And we may be allowed to disbelieve the death of art in India, though, it must be admitted, many murderous attempts have been made upon it.

We are not fully able to say where the earliest building arts came from, of which we see the illustrations in India. There is nothing to show that any distinctive art of this kind was brought in by the intellectual race which, at a remote age, entered India from the north-west, and gradually extended

southwards over their new country. There is to believe that they found architecture among people of the south. In whatever way the Hindus have shown a very admirable forming a style, and working it with great of treatment, and great beauty of detail, the always equal soundness of construction. No reference is made by the historians of the invasion to fine buildings in India at the But the mention of Taxila as a great and ficient city, seems to tell of buildings at th that were of some importance. And now there only the ruins or traces of numero Buddhist topes; and a few other remain are undoubtedly Greek.

Muhammadan architecture, which came the West, assumed more graceful forms than it had done in Persia. It developed ot again when it travelled westward, and in Spain. Moreover, in India, it adopte time of the Emperor Akbar, and under the to some extent of his enlarged and liber Hindu forms of ornament, as well as of tion, in works distinctly Muhammadan, in a manner very effective and beautif similarly, in many parts of India, we fi buildings of recent centuries adopting, or less success, Muhammadan forms of tions, with corresponding ornament. Th appear to have something in commor fundamental ideas, which allows of the tions without marked fault. It is when we see Oriental forms trying Italian features, as at Lucknow, where cases, the mistake is aggravated by th make a good show with inferior means.

The dome and arch, borrowed by son Hindu buildings, are foreign to pure Hi The construction was unknown to the ear builders. A well-known illustration of be seen in the great gateway of the Kutl at Delhi, built in the earliest Path The arch-shaped entrance is not an ar form is given by horizontal courses of a jecting one beyond another, till they would appear that Hindu workmen, un with the arch construction, were em execute the work to a prescribed arch f same thing is to be seen in a cover at the ruins of Rānigatt, a Buddhis monastery, a little beyond our Yusufza to the west of Torbēla on the Indus, ab Likewise in some old bridges in Orissa. pyramidal roofs of Hindu temples in th India have a dome-shaped crown, with dome. It is scarcely necessary to say large Buddhist topes, the large buildin beehive shape, now pretty familiar from and photographs, are not domes, but a on a solid core.

One of the most observable things in c with the best of the old Hindu build groups of buildings, is the attention tha paid to choice of site, and the admirabl which the choice has been made. We a way in which English abbeys and monaste out lovely sheltered spots in which themselves, in green and peaceful vall own land. No less happy has been the the Hindus in the choice of situations

Temples, in shady glens and on all sides, have been placed where they fulfil back-grounds of crag and forest, of red and of varied foliage. Such are Hindu buildings, small and large, in India and Southern India, in Rajputana, and elsewhere.

One of the most noted places of pilgrimage in all India, where so many thousands on the 11th of April of each year, to be sacred waters of the Ganges at the hour, is built in a position to satisfy timement and love of beauty together. It ever issues through the lower hills. And, northward, two little gaps in the next range show two bright snowy peaks away of no more. To the eyes of the pilgrims the sources of the Ganges and the Jamna opened out, as they flock to the sacred spots, amid the temples of Hardwar.

Rarely could a grander site be found than that where stands the temple of Nishat in Kashmir. Slightly raised above the plain, it commands a truly magnificent valley of the Jhelam, with its beautiful range of snowy hills. It was no chance at fixed upon this spot for the splendid Shalimar.

Skilful has been the choice of the locations on which, in the hill country, little other buildings have been erected. One of the top of a hill may be simple in form, but it is not every hill-top eased the Hindu temple builders, nor is the highest point that is taken. Any one made his way up to the temple of Chandhi on the Ganges, or to Raja Hodi's castle at Benares, on the Indus, opposite Attok, or who climbed the long stairs on stairs that lead to the liman at Srinagar, and especially if he had these ascents on a clear, bright morning knows how well the builders have been at an eye that strove to be "satisfied with the better looking up towards the building, on its airy height, or down from it on the wide far-spread scene below.

Many are the positions, well-chosen in like manner, little shrines on the western hills of the Punjab, Sind, most of these being places which, though as it may seem, are resorted to with veneration by Hindus and Mussulmans. Where positions have been chosen as

convenient for Buddhist buildings, monasteries, and topos, or relic monuments, are seldom built on the open plain, even in the neighbourhood of better ground, with no reason apparent for the choice of their positions. The buildings of the Buddhists occupy, of the Hindus and the Muhammadans, the best sites which seem to have been cared for. Some, at least, of those which we might be disposed to think are connected with incidents in the life of Buddha, which may account for the position in which they are built. And probably, have a similar history.

There is often not much room for selection of sites in the wide-extended plains which is the principal no-feature of so large an

amount of Indian scenery. Then in these plains the temple will often place itself in a dark shady grove, or under the shelter of a spreading pipal tree. Or the trees have been planted afterwards, to shelter the temple and its attendants. Again we may see how a fine position on a river bank has been taken advantage of, where a favouring bend of the stream gives a fair view in different directions. Situations of this kind are not without their inconvenience. A big Indian river, and, indeed, a small one too, is sometimes apt to be capricious, self-willed, and strong, and to assert its right to play with its banks in a way that is not good. Benares, Patna, and other places on the Ganges have suffered from this cause. When the British came into possession of the Punjab, the river Ravi was found to have cut away one corner of the large walled enclosure of the Emperor Jahangir's tomb at Shahdara, near Lahore. Protective works that were constructed up-stream succeeded in forming, as desired, a new broad bank, which defends the injured wall against further damage, and keeps the river at a distance. Similar measures have had to be taken in other instances, where buildings near river banks were threatened.

Our building predecessors in India did not meddle much with the large rivers. They had to build some defensive walls and terraces on their banks. Bridges, of course, they did not build across such rivers. Never till railways brought their demand for a continuous running line did the British Government attempt anything more than floating bridges on these rivers in the plains. And when we consider the character of the rivers, and the requirements of a permanent bridge, we have no reason to be surprised that even the wealthy Mughal princes and their engineers did not apply their strength and skill to works of this class, and were content, as their predecessors for many centuries had been, to use boats. The pier foundations of one of our railway bridges were scooped away by the stream, at a depth of 70 feet below the river bed. Another of these rivers, at a place where a railway crossing is being built at this present time, has been known to rise, in exceptional floods, upwards of 90 feet above its low-water level. We can feel, in the face of facts like these, that it was right to let the permanent bridges wait till the days of railroads.

Over swift and rocky rivers in the hill country, which it was necessary to cross by a single span, suspension bridges of hempen ropes or cables made of birch twigs have long been in use. On roads where laden cattle were used, something different was required for crossing the rivers. The kind of bridge called *sanga*, in the northern hills, is a good and useful construction, for which the materials were commonly available. A number of beams, laid side by side, project from each bank of the river, slightly pointing upwards, firmly secured by being built into the bank, and heavily laden at the shore end. Another set of beams is made, in like manner, to project beyond these, and others again till the space left in mid-stream can be crossed by single timbers. It is, in fact, like the overlapping stone construction. On cart roads, where something more is wanted, there are no masonry bridges in large single spans by native builders, such as have now been built in British times. It may be of interest to mention that a few years ago, two brick bridges,

each of a single arch, 140 feet span, were built (by Lieut.-Colonel James Browne, R.E.) over two of the rivers of the Kangra district in the Punjab, on the main line of cart road along that beautiful valley.

In the choice of their materials, we see much to admire in the works of the native builders who have gone before us in India. In the most lively times of Mughal building energy, the free outlay on grand works brought costly stone from long distances, and well has their white marble and red sandstone been turned to account. The most ordinary building materials, being such as the earth supplies, have been the same in all ages. The difference in their use, at different times and places, consists in the choice that is made of the better or the worse, and in the means available, in money or appliances, for conveying what was selected to the place where it was to be used.

When we speak of power to convey what was selected to the place where it was to be used, we observe that in India this power is not often illustrated, as in some other countries, by great buildings constructed of enormous stones. This does not seem to have been one of the favourite ambitions of the builders whose work is now to be found in India. There are, of course, big stones in some buildings, but their bigness is on a different scale from that adopted in other lands, and is not such as to give rise to the admiration which we feel in seeing what has been done elsewhere. There is a big trough at Vizianagar, in Southern India, cut out of a single stone between 30 and 40 feet in length, but it is probable that it has never been moved from the place where it was made. There is a temple in Kashmir which is built of five stones, one for each of the four corner piers, with its portion of roof, and the fifth a square pointed piece, which crowns it. But the whole building is not a quarter of the size of one of the big stones in the terrace wall of the temple at Baalbek.

The masonry of the outer enclosure walls and basements of certain Buddhist works in North-Western India, perhaps the oldest masonry now standing in that part of the country, is of a peculiar kind of effective roughness. It is without mortar. The large stones are unsquared. They have a tolerably flat face, but there has been no endeavour to make them fit each other. Between the stones are irregular gaps of varying width, which are filled in with pieces of slaty rock, all laid flat, and firmly driven home into these wide joints. There are many specimens of this kind of work in the Buddhist tract of the Punjab frontier districts.

There are likewise in India stone circles of upright blocks, like those well known in England and other countries. In one of these circles near the village of Asota, in Yusufzai, north east of Peshawar, about 50 ft. in diameter, the stones have been roughly hewn on two sides. Their greatest thickness is about 2 ft., and the greatest height of any now standing is between 11 ft. and 12 ft.

It is remarkable how little (speaking generally) even the oldest buildings in India have suffered from exposure; and this exposure is sometimes of a very trying kind. The buildings bear testimony to the good choice that has been made of the stones used in them. A dark and hard blue limestone has been a favourite material with the Hindus. It receives fine sculpture, and retains sharp, well-defined edges. Much of the Buddhist sculptured work in the

north-west of India, where sculpture is v  
dant, is on hard clay slate. The sculpture  
buildings is mostly on the interior faces.  
temples at Dilwara, on Mount Abú, prof  
beautifully carved inside, are of white  
Outside, these buildings are of studied pl  
not as the Hindu buildings, great and sma  
parts of India, which carry much ornam  
outside. The largest of these—the mag  
temples of Tanjore, Trichinopoly, Tir  
Madura, and other places in the south, of N  
the west, and of Orissa in the East—being  
throughout with elaborate carved ornam  
sculpture. On the hills of the Salt Rang  
Punjab (hills containing the great mines  
salt) are Hindu temples of a grey li  
naturally of a somewhat honey-combed  
which has suffered further from the weat

In the great imperial cities of the Mugh  
marble and red sandstone have been lar  
together, and with excellent effect. The  
polished, and well withstands the weat  
though it suffers little from the weather,  
another kind of injury, very subtle and  
some, to which it is exposed. However  
and closely the stones have been laid, ye  
joints between them, on domes and terr  
on cornices and parapets, the seeds of al  
trees will find their way, and there begi  
and thrust their roots beneath. The pi  
particularly insidious in this kind of att  
watched stone-work, and if allowed to s  
see it has been sometimes, it will al  
strongly, dislodge the stones, and, if the  
near the foot of the building, will pus  
roots through the wall, and down to  
moisture that it seeks.

In the Muhammadan buildings of A  
later reigns—the seventeenth century  
latter half of the sixteenth—the red sa  
very largely used. There are buildings  
date, now six and seven centuries old  
this stone, frequently bearing Arabic i  
in raised letters, is still sharp-edged and  
contrasts very favourably in this re  
many buildings in England sadly c  
weathering of the sandstone. Oxford  
looks more venerable where the edges o  
are worn and rounded, and the form of  
ings lost; but it would have been be  
had not happened. There are buildin  
country of a sandstone much resembling  
and general appearance that of the Mu  
in Northern India, but very different in  
The exposed masonry of the Church of S  
at Coventry, is seriously worn away, an  
be crumbling continuously now. In  
endeavour has been made to hold tog  
iron straps parts that were in danger of  
and in some of these places little mor  
iron strap now remains.

In the Indian buildings in which l  
marble and red sandstone are used, the  
colour is sometimes given by the use of  
ent materials for different parts of the  
sometimes by using them together, in  
bands, or otherwise combined. Colour  
shown in the Muhammadan buildings  
work in the piers of the arcades, the  
the arches, and other parts, and by lim

inlaid in the white. The inlaid work is on a large scale in some buildings. The chiefly used are blood-stone, carnelian, and The inlaid work, besides that on the borders and elsewhere in geometric figures, is representation of flowers in conventional and often with much freedom from the rigid style which prevails in most Oriental designs. In the Persian or Arabic characters the inlaid or carved in raised letters, not red like our inscriptions. In the interior of the reception halls of imperial buildings, and the ornate private apartments, gilding also is used. But some of the most beautiful of the Muhammadan buildings, are those in which there is least colour or applied decoration of any kind, so elegant are the forms and so just the proportions of the several parts, so refined the execution, and so true the execution. One other feature of ornamental work of much beauty is to be observed in these buildings, the green-work of open tracery—large thin slabs of marble or sandstone, pierced with geometric of great variety. Very good specimens of this kind of work are to be seen in the Indian Museum of the South Kensington Museum. A comparatively small variety of colour thinly on the outside of the Taj Mahal at Agra—an building perhaps best known in England—because of its having frequently been felt, at least, to be heavy. It is not really unrelieved by the white. Besides some inlaid coloured work, straight lines of black marble inlaid, black lines on the thin engaged pillars at the base of the inlaid ornament following the outline of the arches, and encircling the neck of the dome, and inscriptions in large letters. But so much is the mass of white marble, that the colour afforded is comparatively small. A little of the building reconciles the spectator to this whiteness, and only leaves him full of wonder and admiration at the beauty as well as grandeur of the work. Its surroundings are on a scale of corresponding magnificence. The great square entrance with its splendid gateway, and the minarets on the corners; the straight-lined garden and its narrow channels, with shallow stream of water and rows of fountains in the middle; the lines of tall dark cypresses, with trees of varied foliage and colour throughout the garden;—it is with these things about it, and a sense of its stillness and solemnity over the whole, that we look at this magnificent marble tomb. We feel how large a measure of respect and admiration is due to the men who did all this, to those who purposed and devised a monument on a scale of grandeur, and those who executed it with such inner worthy of the conception. Have not we reason to be glad that the wealth of building in those days threw itself into forts and palaces, mosques and tombs, pleasure gardens for the rulers, and serais for travellers? What should we have lost if Shah Jahán, for instance, had been content of smaller and more modest aims, and had stowed the best efforts of his architects on the building of court-houses, town halls and barracks, and schools and hospitals? Their time has come. It is better for art, that Shah Jahán had his something else. The world has gained. The use of colour enhances the noble massive-

ness of the Taj; we feel this to be in agreement with the nature and purpose of the building. The use of colour on Mughal buildings was well understood and very general. In the beautiful and wonderful city at the head of the Adriatic, which so many travellers to and from India have nowadays an opportunity of seeing, we find a large amount of colouring of buildings, most of it very Oriental in character. But India has nothing to show of exactly the same kind. Buildings of brick, in India, if not faced with stone, were thickly plastered, and the colouring was given by figured designs, not whole surfaces of colour, or by a facing of glazed work, which is of two kinds, on pottery and on plaster.

The use of glazed tiles and glazed plaster seems in India to be most frequent in the western frontier provinces of Sind and the Punjab. But there are many good specimens at Gwalior, Delhi, and elsewhere, of buildings thus coloured. The work goes by the general name of *Kāshī*. Glazed tiles are used when a large surface is to be uniformly coloured. Patterns also of different colours are given on single tiles. The glazing on plaster is used for coloured devices, made up of separate small pieces, of the different colours. And these are laid on and cemented on the surface of the building. The plaster, which is made of lime and sand, receives first a very thin coating of glass containing lead, which both gives a fair smooth surface for the coloured glazing that is to be afterwards applied, and enables it to adhere. Both these arts seem to have been imported from Persia. The earliest specimens of glazed tile work known are at Mashad and Tabriz. The name Green Dome (*Sabz Gumbaz*) which is given to a conspicuous building at Mashhad, of which the city is proud, is also borne by a tomb at Lahore, of which the green covering of the dome is in good preservation. Another at Lahore is similarly called Blue Dome (*Lila Gumbaz*.) The cities of Multan in the Punjab, and Tatta, and Hyderabad in Sind, and others, have good specimens of this kind of work, as well as of the plaster *Kāshī* work used for wall decorations and inscriptions. Lahore has many of great excellence and beauty, the most complete is the mosque of Wazir Khan, in the heart of the city. The figured tile work is now carried on in Sind, at Tatta, on the Indus, and at Hala, 30 miles north of Hyderabad. The Masjid, built by Shah Jahán, at Tatta, has had the deficient tile work lately restored. At this place there is no glazed work of the other kind, that is, on inlaid pieces of plaster.

Indian brick-work, except in wells, is rarely seen, for it is always covered, or meant to be covered, in one of these ways. Its quality is excellent, though its appearance is coarse, as it was not meant to be seen. Well-burnt bricks are united by well made but rough mortar, the mortar courses being of great thickness, often much thicker than the bricks, giving the work the appearance almost of a concrete wall with thin bands of red brick. It is indeed a concrete. A similar material is used for terraced floors and roofs. And there are places where, the wood and tiles on which it was laid having decayed and fallen away, the terrace covering has remained, spanning the gap, as a single block of artificial stone or concrete bridge.

In stone buildings in various parts of the hill countries of India, the insertion of horizontal beams at intervals in the masonry, which is a common constructive arrangement, gives a pleasing variety to the outer face of the work, like the use of stone of different colours. The practice is similar to the use of bonding courses of red brickwork, which we see in Roman walls of stone masonry in Britain. This was well shown in the old wall lately discovered in extending the railway buildings in the neighbourhood of the Fenchurch-street Station. The bright red bands were of tiles or bricks of large size, of which there were three courses in each horizontal band. Similar bonding brickwork of bright colour is to be seen in a massive Roman wall at Leicester; of which English builders have taken advantage in a very practical way, by using part of the materials, both brick and stone, for the adjoining church of St. Nicholas. In the church the construction is repeated, stone masonry with courses of brick at intervals. The cathedral of Carlisle has in like manner helped itself to stone from a neighbouring Roman wall.

In these cases, as in many others, perhaps no great harm was done, as the walls were plain and uniform masses of solid masonry, interesting chiefly on account of their history and their construction, and having plenty of the work still left to satisfy this interest. But the practice is a dangerous one. It has been often followed, in all countries, and has sometimes not been quite so harmless. We cannot tell now what we have lost at old Delhi. Bernier says, Shah Jahan's new city, which was being built when he was there, was conveniently near the old one, which supplied quantities of building material ready for use. Very likely the honest intention in the first place was to take only the stones from absolute ruins. But we know how difficult it is to get any rule of this kind rigidly adhered to, and to prevent the despoiling of buildings which, if in a sense ruins, are yet ruins to be carefully and tenderly preserved. And these Mughals, though they showed admirable taste in their own works, felt no obligation to spare Hindû buildings on account of their beauty, even if they always respected those of the Pathans. Zealous Muhammadans, from time to time, have reckoned it no less praiseworthy because it was convenient, to destroy temples and other works of their idolatrous predecessors, though they did not often use the materials again on the spot in so pretty a piece of reconstruction as the colonnade at the Kutb, near Delhi. Muhammadan buildings, again, have been subjected to the same treatment. Ranjit Singh's marble *baradari*, or summer-house, in the palace gardens at Lahore, is certainly a very graceful building as it is, though rather too large for the enclosure in which it stands. But we cannot, therefore, excuse his robbing for this purpose the tomb of Jahangir at Shahdara.

Of a too indiscriminate freedom in using materials of old buildings, even English engineers in India have sometimes been accused. There are stories (Mr. Fergusson knows some of them) of English officers having turned to ignoble uses fragments which were of real worth and interest, and which, in time of pressing need, were appreciated only for their immediate usefulness. I am not prepared to say

that such things have not been done, though not myself know of any instances. There are many places abundant supplies of old materials, particularly old bricks, which, being taken from absolute ruins or worthless buildings, are of plainest kind, or dug out from the foundations of old towns and villages, can be freely used in new works. And this use of such materials, which might give cause of unpleasantness to the tenderest antiquarian, or call forth remonstrance from the most protective antiquarian. But it has not been easy to draw the line, or make a contractor keep to it.

Besides defence of good buildings against spoliation, protection against natural decay is also needed. Whatever have been the shortcomings of the British Government, and the of British officers in India, in times past, with regard to the care and preservation of old buildings, it is not now to be said that the matter is neglected. The works which it is desirable to guard against decay are in such number and of such size that all can be done at once that is necessary. The arrangements with this view have, for the past, been made more systematic, and are now being brought more fully under the management of the Government. Everywhere attention is now paid to the subject, and local measures are taken to arrest the progress of decay. Restoration is not now except in some very special cases, but is made to preserve from further injury and the hand of man has spared, of buildings we desire to save on account of their architectural or historical interest.

India is generally believed to be a country in which has been very stationary in certain many arts being practised in the same manner now as long ages ago. In regard to building, this is probably not more true of India than of other countries. Until the introduction of machinery, we commonly understand by machinery, all ordinary building work was done for the most part with hand tools, as very many things are done still, these common operations are essentially the same everywhere. They are the same in some particulars, as for instance, in the common use of the foot for some parts of what we are accustomed to call manual labour, and the practice of the ground for some kinds of work which artisans do standing. But, in the main, the reason to believe the operations and the materials to have been much the same for long ages in all countries alike which have come to use any such arts. Sculptures and pictures of something of modes of working in ancient Egypt and Assyria. Written accounts tell us that, more than 2,500 years ago, in the land between the Nile and the Tigris, the smith used to work with coals, and fashion the hot iron with the hammer, and the carpenter stretched out his rule on the ground, marking it with a line, then fitting it with the compasses; which briefly and aptly describes the mode in which the same crafts work in all lands in the present day. The same may be said, no doubt, of the hewers who, three centuries earlier, came to Tyre to build the king's house at Jerusalem, when we come to see the scale on which

sewing work was done, without such helps as we have now, that we admire and persistent way in which immense and only by simple and primitive applied to overcome all difficulties in it a settled purpose. The labour on building works in India has not kind. We see that it was of a kind other qualities as high, always more direction of artistic feeling than of exert enormous power.

se old Indian buildings, sometimes a and sometimes not much, is to be in the people you find about them. mes know nothing that you want to ers will tell you a great deal which tter not put down as quite correct got it on the spot. But you may much from a humble informant that ou to an understanding of the thing oking at. A deal of intelligence edge is often to be found under the age-brown costume, or the more simple white ashes. We can tolerate, for a is not attractive, when we find how is along with it that is better than it if we have learned something about ; that has engaged our attention, we better, and so is somebody else, for our

It has drawn out something like regard to an object that has at least on interest for the Indian fakir and the ristian. We have gained more than from the opportunity the old building chat with an unenlightened, perhaps, thless, fellow man. The sympathy, if ad imperfect, quickens the desire for that shall be fuller and better.

few people who have spent years and have seen a good number of the people that were there before ave not brought away with them ad pleasing conviction that these old e men who had a true knowledge of nstructively good, and a true sense of rtistically beautiful. It is good that s who go to India, and who care for , should know how much there is in gs of that country that will have an them. This is only one, however, of the classes of objects which India displays ks us to look at. I would not present it of the most important and most interest- any objects of interest and importance. ire rather to show that there is much at no one need want in India local nterest to engage some portion of his tention. It is well, when the hands atisfaction of useful work, to find some nd us, apart from that work, whatever will pleasantly help to fill up some of ours, and thereby lighten the hours of ays with the aid of recreations of some are quite as needful in India as else-

particular classes of objects are, to me is to turn his attention, depends on opportunities. It can seldom be that s will not yield something. To one, own products, in the garden and the

field, on the hill and the plain, supply unfailing sources of study and enjoyment. To another, the investigation of the earth itself. To another, the field sports of India afford the means of seeing and knowing many more things, besides the creatures which are the objects of the chase. One in the languages and literature of India finds ample material for profitable research; another in the arts and manufactures; another in the history and antiquities; another in free intercourse with the people and the study of their local dialects, their personal and social customs, their traditions and stories, their proverbs, and their songs. In all these ways one learns to know also something of the thoughts of the people, their feelings, and their wants; and, let me add here, always in so doing, learns to think more kindly of them. This, and much more there is, in the records of the past, the life of the present, and the needs of the future, to supply matter of deepest interest to every English sojourner in India.

It is needful sometimes to notice this, for there are some people who cannot believe there is anything in India in which they could manage to get up an interest, or which could help to reconcile them to the country. They make up their minds there is nothing there for them to like or care for, and a great deal to object to. And there are things to object to. An English traveller of the early part of the seventeenth century, the chaplain of Sir Thomas Roe's mission from James I. to the Emperor Jahāngir, devotes a chapter of his book to what he calls the "discommodities, inconveniences, and annoyances, that are to be found or met withal in this empire." And he goes on to tell of them in detail. There have been many improvements since Edward Terry was in India, but "discommodities" and "inconveniences" there are still. Snakes and scorpions have not been abolished, though, indeed, you do not see them so often as some people have supposed; there are still mosquitos and sardflies, as well as other small insects; there are musk rats and white ants; there are dreary wastes and dirty dust-storms. And it is sometimes very warm in India. Yet, somehow or other, with all these things and many more, it is not a bad country after all, and, as Terry himself properly adds at end of his chapter, there are also "commodities and contentments to be found in those parts."

Much of what we now find to delight us has been created since his time. Akbar's grand administration was then over. Shah Jahān's magnificence was yet to come. The two centuries that have gone by since his day, have made a great difference to us, and to the people of India, and have greatly helped forward the knowledge of many of the things of interest I have referred to, which present themselves to us in the present day. I do not press the claims of any one above another. Each has its interest, and will get people to care for it. Whatever the line each person may take, who cares to give attention to his surroundings in India, all I am concerned here to say is,—don't forget sometimes to look at the old buildings.

#### DISCUSSION.

Mr. B. Haughton, C.E., said that on a previous occasion he had mentioned in that room the Taj Mahal

as being the work of Indian architects, and brought it forward as an instance of the extraordinary architectural capacities of the people of India, whereupon he was contradicted, and told that the Taj was built by Italian architects. He should be obliged if General MacLagan would give his opinion on this point. He had since consulted the *Encyclopædia of Larousse*, in the British Museum, in which it was stated that the Taj Mahal was a marvel of Indian art, that it was built by Shah Jehan, in honour of his wife, that it consisted principally of white marble, was commenced in 1631, occupied 20,000 workmen, that the marble was brought a distance of 200 or 300 miles, and that the expense was 80 million francs, it was also stated that some persons pretended that a Frenchman, known in India as "the marvel of the age," laid claim to the paternity of this *chef-d'œuvre*, which had not a rival in the world. He had been much struck with General MacLagan's description of the thin brickwork, with a thick layer of mortar between, so different to the mode of building in Egypt. He had tried in vain to insert the blade of a penknife in the joints of masonry in the pyramid of Cheops. He had roughly calculated that the large stone in the ruins of Baalbeck spoken of, must have weighed about 800 tons. They were accustomed to large stones in Egyptian buildings, and other ancient ruins, as, for instance, those at Tadmor. It was very satisfactory to hear that the specimens which had been produced were not taken from actual buildings, but, unfortunately, a different spirit sometimes prevailed, for he had seen large pieces knocked off the Cleopatra's Needle now at Alexandria, with a geological hammer.

General MacLagan said it had been ascribed to European architects, and the question had been much discussed, but opinions were most in favour of the conclusion that the Taj Mahal was a purely Oriental construction. He should have a very high opinion of the French architect who had designed and constructed such a building. With regard to the style of the masonry, he observed that stonework in India was quite as fine as that in Egypt; it was only brickwork that was laid with such thickness of mortar as he had mentioned. The habit of Englishmen and others of bringing away specimens of anything remarkable or interesting was very general, and he could quite believe what had been said about pieces being chipped off Cleopatra's Needle, for where it lay many years, half buried in the sand, it presented tempting facilities to visitors of this class. Some travellers left their mark without taking anything away, and at Baalbeck, on the building containing the magnificent stones he had mentioned, he had seen names painted in letters a foot or fifteen inches high.

Mr. Thornton C.B., said he thought he could clear up the question about the architecture of the Taj. In the itinerary of Manrique, a Spanish monk, who lived some time in India, in the time of the Shah Jehan, it was mentioned as then being built under the supervision of an Italian architect, named Geromino Veronco. He stated that Geromino was asked by the Emperor to make an estimate for the construction of Taj, and accordingly, with the help of native architects, he made an estimate, and gave the cost at 3 lacs. The Emperor said that would never do, he could not have a building of that cheap description, whereupon Geromino retired, and after a time produced an amended estimate of 19 lacs, which was eventually accepted. This Geromino Veronco was afterwards sent to Lahore, probably to superintend some works there, and there he died. With reference to the art called *Kashi*—the coloured tiles, which formed so prominent a feature in so many buildings at Lahore—there is a tradition there that it was introduced by the Moguls from China, originally through the influence of one of Timur's wives, who was Chinese. The word "*Kashi*," he was

told by those conversant with the subject, was from an Arabic word, signifying a porcelain.

Mr. W. Simpson said that the last speaker had so far an explanation about the building of that there were foreign architects who engaged on the work; but he believed when went to Agra, Veronco was dead, and the been then taken up by another Italian, and Full information on these points would be in small article, by Judge Keene, in the 11th new series, of the "*Asiatic Researches*."

Mr. Thornton said he had supplied Mr. I the information.

Mr. W. Simpson said it had been generally that a Frenchman, Austin de Bordeaux, had nected with the Taj, but he supposed that Manrique had settled the point as to the European art on that structure. He (Mr visited the Taj in 1860, at that time the as been mooted, but he had no need to look k information as to whether it was the work architect, for foreign art was written on it as palpably as could be. He had no doubt saw the ornaments, the inlaid work in the as well as in other parts of the building, t artists had been at work upon it. It was at the building of the Taj, that this flow of ornament came to India, and it had res ever since. The design of the Taj was similar to other designs of Mahomedan India. He could not give to the Taj the which some did, it seemed to him to be decadence of Mahomedan architecture, you came down to the stage which at p be seen in Lucknow, where it became al and plaster, and ceased to be worthy of architecture. The Taj was not to be c real art with the older work about Delh sidered that Indian Mahomedan archite almost with Akbar; it was at this ti Mahomedan had combined in a most beau Hindoo forms with his own, and then foreign European style, which never amalg the Indian, and the Indian art decadec state it was now in at Lucknow. He had l very great pleasure indeed to General MacL especially as he had been to nearly all th had mentioned. He had ferried across a morning such as had been described, and the picturesque boats. He had crossed t Bridge on the Sutlej, which was similar described by General MacLagan, and had bridges of rope, and had drawn the pres the old Masjid at Delhi, to which refere made. To know the building arts of Indi have travelled in India, which he had had of doing, so as to realise the amount of bu had been done in that country in the past, there were about 40 square miles of ruins, wandered about sketching them, he thought medans were really the great men of Indi went the next cold season into Rajpootana upon the old city of Chitoregurh, the amir Mewar, where there were ruins about three and a mile wide, of the old city which t left when it was sacked by the Mahomed had remained ever since, and it was cert wonderful place, and since seeing it, he doub Mahomedans were the greatest of Indian They were certainly great, and the ruins Delhi were undoubtedly the most beautif remains. There were many other places wh of buildings were found. On the site of was said you could not dig for twenty mile without coming upon bricks, which would idea of the extent of the ancient towns. In

re ground, the Archaeological Survey being some of the old cities. He might say that there was no country in Europe, or of the world, to compare with India in building remains.

He thought that, in their enthusiasm for must not be too hard on the present for not producing works of a similar kind at the cost of the Taj at three millions instead that with the amount of money this more utilitarian age—for railways, results to show. We had spent about £100 on railways alone in India, which was £40 Taj; and, besides that, there were works of utility, such as irrigation, seen constructed.

Sir Joseph had listened with very great interest to the paper, as it revived the charming memory of his 22 years' residence in India, and of many of the most distinct features. Many people, talking about India, said that they had been there, and he was very glad that MacLagan had read this paper, which was such a statement. When one saw the ruins of Old Delhi and the Kutub, the ruins at Agra, part of which were served in the fort; or the old city of where there were certainly some very good sandstone; or the beautiful carved work in many places, mostly of the time of the Mughals, it was nothing to be said.

One thing had impressed him very much, the North-West Provinces and went was that the art of constructive building had ceased with the Mohammedan Empire. At Lucknow were, for the most part, ruins in comparison, consisting of mud and brickwork. With regard to the thought he had seen somewhere that the art of native builders, although they designed it; but he believed the truth was that the decorative work, the inlaying, carving, &c., whilst the main design of the building

was, V.C., C.S.I., wished to make one more of an observation made by General MacLagan which had also been referred to by Sir Joseph, that since the English rule in India had constructed no important new buildings, this undoubted fact was often put forward as a reproach to the English Government, however, that this was not a fair statement. Before the English rule in India, it was impossible for anyone above the common cultivator of the soil to live in an India where life was not secure enough, and the laws of the country, were forced into and when they congregated there it was only to be distinguished themselves by their wealth in palaces or mosques, or tombs. But when the English rule was established, in proportion to the safety of the people, they left the cities of the country, to occupy themselves in agriculture, in a way they had not been able to do for three centuries before. He had on two occasions seen cities nearly depopulated, but he was certain that it was caused by the prosperity of the cities.

Again, in reply, said there was no doubt that Sir Joseph had said was, to a great extent, what he had said in the paper that, except in the case of the occasion for erecting grand buildings, and also the means available to be used. There were some beautiful buildings, Sir Joseph Fayer had observed, at

Fatehpur Sikri, built with large stones, and there were large stones in many buildings in India; but their size was on a scale very different from those at Baalbek, the great arch in Jerusalem, and other places. He agreed very much with what Mr. Simpson had said with regard to the change in the style of architecture after Akbar's time. The builders of his day adopted Hindoo forms with remarkable success. There were some specimens of pillars, corbels, brackets, &c., of Akbar's time in the Indian branch of the South Kensington Museum, which were of great beauty, and would show exactly what Mr. Simpson referred to. There was a certain massiveness about the architecture of that time, which he quite agreed you did not find afterwards. Still, the beauty of such a building of later days as Jama Masjid, at Delhi, the elegance of form, and proportion of the domes, the minarets, and cupolas, and other parts, was undeniable. He had with him some photos, in which the beauty of the details of buildings mentioned by Mr. Simpson was remarkably shown. Mr. Simpson had observed these things probably with more attention than any gentleman in the room, and the results of his observations were of much value.

The Chairman then proposed a vote of thanks to General MacLagan for his admirable paper, which was carried unanimously.

#### NINETEENTH ORDINARY MEETING.

Wednesday, May 4th, 1881; Lord ALFRED S. CHURCHILL, in the chair.

The following candidates were proposed for election as members of the Society:—

Bonar, Lionel Ninian, 75½, Old Broad-street, E.C.  
Butler, Lieut.-Col. Henry Thomas, 66, Prince's-gate, S.W.  
Campbell-Walker, Capt. Arthur, Ashley Warren, Walton-on-Thames.  
Gibbs, Sir B. T. Brandreth, 13, Pelham-crescent, South Kensington, S.W.  
Hudleston, Wilfrid H., M.A., F.C.S., F.G.S., 23, Cheyne-walk, Chelsea, S.W.  
Lee, Charles John, Fairlight-villa, Sydenham-road, Croydon.  
Nesbit, A. Anthony, F.C.S., 38, Gracechurch-street, E.C.  
Nevill, Lady Dorothy, 45, Charles-street, Berkeley-square, W.  
Stirrat, Robert B., 7, Grey-street, New-castle-on-Tyne.  
Walkinshaw, William, Hartley-grange, Winchfield, Hants.

The following candidates were balloted for, and duly elected members of the Society:—

Beattie, William, London and South Western Railway Works, Nine-elms, S.W.  
Cockburn, James, 11, Heathcote-street, Mecklenburgh-square, W.C.  
Crossley, John Thomas, Q.C., 91, Cheyne-walk, S.W.; 4, New-square, W.C.; and Junior Athenaeum Club, S.W.  
Gibson, Joseph F., Clovelly, Woodchurch-road, West Hampstead, N.W.  
Goodwin, Thomas, 12, Southwark-street, S.E.  
Law, James, 544, Oxford-street, W.  
Lovett, William John, Carrer-street Works, Birmingham.  
Lyell, Francis Horner, F.R.G.S., Nettlestone, Widmore, Bickley, Kent.

MacGregor, Alexander, M.A., 6, Charles-street, Berkeley-square, W.  
 Powell, Frederick, F.R.G.S., Bakewell, Derbyshire.  
 Pupikof, Oscar, 28, Finsbury-square, E.C.  
 Stubbs, William Henry, 3, Winton-square, Stoke-on-Trent.

The paper read was—

## BUYING AND SELLING: ITS NATURE AND ITS TOOLS.

By Professor Bonamy Price, M.A.

Buying and selling are matters so plain, that it almost seems idle to ask what they are. They are things done by everybody every day. Yet in the practical world, the most familiar things, though they may have the greatest importance for human life, are often the least understood. They are the very region where confusion and mischief dwell.

Look, for instance, at the different senses given to the word money, and the power which the ideas attached to it exercise over human life. Yet how many can answer—What is money? and how is it that it buys?

First of all, let us inquire whence came buying and selling? How is it that they are so universal amongst human beings? They spring from the most peculiar and characteristic feature, the greatest power of civilised life, division of employments. I will make this for you, if you will make that for me, is the basis of civilised existence, is the root of all progress. Hence it is that exchange is the very core of political economy. Division of employments enables each man and people to perform that work for which each of them has a special aptitude. It creates skill, develops machinery, obtains larger and better results from the same labour, then reduces the cost at which they are made, and consequently vastly diminishes price. By dividing out the work to be done amongst each other, mankind acquires more wealth and finer quality at the end of the day's work.

The first consequence of division of employments was barter. But a most embarrassing difficulty immediately presented itself. How could the men who mutually wanted each other's goods be brought together for exchanging? On a large scale, as society developed itself, and employments grew in number and distance, that was impossible. How could a farmer have found a tailor who would give him a coat, or a shoemaker who would give him boots, in exchange for a calf or a sheep? What could the tailor have done with the calf? Exchange would have stuck fast, and only a petty village life would have been possible. The difficulty was solved, and civilisation won, by Indians. They invented money, a money made of skins. The perplexity vanished. The career of trade was opened for the human race. The mighty machinery of division of employments was established.

The savages invented a true money. They consented (to use the language of city men) to buy and sell with skins, and these skins tell us what money is, and how it works. The skins were commodious pieces of wealth, useful, and consequently valuable. They cost labour to produce, and that gave them worth as against other articles. The

trouble of the day's chase, the food it cost value to the skins. The skins would not cured, much less given away, without caution; in economical language, they had value—value in a market, value in exchange—instinct of the Indians made them willing skins as money. Each man knew that all would take them in turn as money. There was always sure of getting food in exchange for them. Every man who took them could please—just as the gold of a sovereign-moment make them cease to be money, and use them as things for use. The skins reveal the mental truth, so generally unperceived, of the nature and the working of money. It is not an instrument, a machine—absolutely else. There is no fact about money of more importance to grasp than this, simple and obvious though it seems to be. These skins were taken to be worn; they were intended to pass from man to man, for working out this peculiarity, that they could do work for each man. That is what is meant by exchanging. This is precisely what a sovereign does. It is a pure tool, of no other use, so long as it remains a sovereign, and is used by only bankers and merchants would a sovereign's mind to be penetrated with this truth, coined as money, is an idle, useless thing that does work as currency. The skins were for handling; so does a sovereign, but when it has performed services well worth the trouble, the sovereign does nothing else but pass from hand to hand, precisely as a locomotive or a horse-drawn carriage are worthless things, until they perform the work for which they were intended.

Now we can answer the great question which city finds so hard to answer—How is it that a sovereign buys a hat? You cannot pay attention to the answer, perfectly simple as it is. It buys because it costs as much as the expense of carriage to bring that small piece of metal from an Australian mine as it costs to get the materials for a hat, and to manufacture a hat. The whole mystery of money vanishes. There is no better money than a sovereign. The gold buys by means of its cost of production, certainly not, as so many have said, by its stamp as a coin. The stamp only shows that it is made of good metal of the right weight. The hatter sells for a sovereign, because, in the words of Aristotle, he knows it to be a useful thing. He gives away the hat for a piece of metal, which he can convert the sovereign, if he likes, into wearing. He relies on the assurance of the metal, that gives him the important assurance, that other sellers will give him goods of the same value as his hat, will give him articles worth the metal he has given for the sovereign, that is, worth his hat. It is the metal which buys; the word money is not necessary to explain the fact. That this is so, is proved by the daily fact that nations pay their trade to each other in bullion; they are willing to give the amount of uncoined metal for the money due.

But though skins are real money, and the true nature and mode of working of money, still they are not good money. They are

fast, are of uncertain supply and value. The best material yet known to make this is hard, pleasant to handle, very light value, divisible into parts, can be re-ack into a commodity easily, and, above the greatest of qualities for serving as steadiness of value. For the innumerable investments expressed in money which in modern life, the payment of the same was estimated at the time when the debt is, is of the most supreme importance. It held by many that gold itself has become but it has never been definitely proved. Is for discussing this most complicated

we can see clearly that an act of buying is of barter, the substitution of double for other. The sovereign is first bartered for and is re-bartered by the latter for an other. They have been exchanged by the use of the tool money. Further, money is the means of measuring the values of things against each other. All have their money. Thus the value of a £30 gun is but 30 times greater than the value of a pound of convenience of such measurement is

attention must be drawn here to a fact of importance; good money works by the cost of the metal it is composed of; but the value of many articles are determined by the cost besides cost of production. That is, the value is given; but a power often comes which varies price, expressed by the value in the sense derived from the verb, I value, is a feeling, and is the greatest force in political economy. It denotes the esteem felt for an object, the amount of caring for it, the power which determines how great is the value; which a buyer is ready to make to obtain it, how large the compensation which he is given to a seller for the sacrifice of parting with it. This feeling is attached to every article, and it is to many it adds a price far higher than the cost of production. A Raffaele picture, a diamond, an old marble, a distinguished autograph, and the like, sell for immense prices, depending on feeling more or less fanciful. They are not worth excessively bad money. A buyer given £10,000 for a Michael Angelo, has no security that he could change it for anything like that value. Ordinary production is a determinate quantity, and the value is for all. It thus can increase all value, depending on feeling or other.

A cardinal fact, that money—a sovereign—is not a tool only, is full of instruction. In place, it kills off the mercantile theory that we have to hear, that exports ought to exceed imports. A more foolish idea cannot be imagined. It denotes that the goods of the traders are sold, and there they stop. If only they get hold of the money, they ask no questions; they feel that they can now do what to do with it; they can buy what they like. But is the country the richer for the use of coin? Could these good people be made less, if they had been paid with gold instead of money? Is a farmer the richer, or is it him to have as many carts as he wants, if

he is paid for his wheat in carts? Oh, but a farmer could not get rid of his excess of carts easily; there is no trouble in buying with money, if only the money is in hand. But what becomes of the money thus acquired by an excess of exports? The answer to this question depends on another. How many coins, how much gold, does a nation require, and is able to use? The answer for money is the same as for carts or hats. How many hats does England require? Clearly as many as there are heads, and a few to spare. What, then, is the thing which corresponds for coins, as heads for hats? Plainly, the buying and selling carried on by coins, including those needed for banking reserves. There must be currency to perform that work fully, else great inconvenience would arise—some to spare would also be advisable against unforeseen contingencies. Beyond this quantity the tools are useless: they have nothing to do; then what becomes of them when brought in by an excess of exports? So long as they remain in England, they are locked up in the Bank of England's vaults: they are wealth for the time annihilated. Meanwhile, how has it fared with England in respect of the exports for which there is so much rejoicing? They consumed a vast amount of wealth in making: food and clothing for labourers were used up, coals were burnt in profusion, materials worked up, and all is gone. What has England in return? Some metal locked up in cellars. As long as it remains in England, she is the poorer for these exports. The wealth returns only when the buried gold goes abroad to buy, and then the imports will exceed the exports, and the country is made the richer. Imports alone enrich a country, not exports. To buy gold which cannot be used is as pure an impoverishment for the time, as if the purchasing goods had been given away for nothing. The question always is—Is it worth while to buy this unneeded gold?

We now pass on to paper money—bank-notes. Time fails to examine this form of currency in detail. I will only remark—

1. That there is a large gain to the country by substituting for sovereigns tools costing sixpence for doing the same work.

2. But how is it that paper can do the work, if it be true that money works by double barter, giving value for value? Is this view unsound? Not so. The explanation is to be found in the fact that a sovereign works, not by using the metal of which it is composed, but by the value which it possesses. If twenty persons receive the same sovereign on the same day, each has had the worth of the goods he sold, but the sovereign remained unchanged. Each seller knew that he could melt that sovereign into gold metal and barter it as such, but he did not. The knowledge that he could do so sufficed. Hence, if the sovereign had been placed in a kind of cloak-room, and the ticket received for it had circulated in its stead, the work of exchanging would have been effected equally well by the paper tool. The ticket gave the power of obtaining the metal when desired; that sufficed for each seller.

3. This shows the extreme importance of the sovereign being at hand when demanded. Inconvertible bank-notes are a bad money. They are sure to be issued in excess of what the country wants for buying with. Their value

then becomes depreciated, and very variable. The relations between debtors and creditors, between shop-keepers and their goods, become vitiated, to the great injury and loss of the whole country.

We have now reached the third great instrument of buying and selling—banking. To show its vast importance and power, it is enough to say that payments exceeding 100 millions of pounds are made in the City every week by the Clearing-house, without a penny of money being used. On no other subject connected with trade does such deplorable confusion exist as on banking. What, then, is a bank? a question which few indeed know how to answer. It is an intermediate agency between a lender and a borrower. A banker is best understood if looked upon as a broker between two principals. He brings them together, just like a stock or corn-broker. With what he receives from his customers he first pays the orders for money which that customer makes upon him with pieces of paper called cheques; the remainder he transfers to a borrower. Does he make those payments with money? Does a banker deal in money? Most certainly not. One fact is conclusive on this point, besides the evidence of the Clearing-house. Sir John Lubbock has shown that only three pounds in every hundred were received by the great banking-house of Robarts in cash, and of those three pounds, ten shillings only were money, metallic money. How can a banker pay £100 with only £3 of cash? He does not, and cannot pay the remaining £97 with money. This fact is decisive—a bank does not deal in money, does not receive or pay money, if the word money is to retain its real meaning. How then are the £97 repaid to the depositor? Here lies the secret of all banking. To understand this is to understand banking. Let us consider a complete banking transaction from its origin. A farmer has sold £1,000 worth of corn, and is paid with a cheque, say on Glyn. He places that cheque to the credit of his account, say at Smiths'. How do Smiths obtain payment of this order for money? By asking Glyn for sovereigns? Nothing of the kind. They send it at once to the Clearing-house. This is an office to which the City bankers send the cheques which they have to receive from each other. Every two hours a list is made out for each banker of what he has to receive, or has to pay on the cheques sent in; he settles the balance by receiving or giving a cheque for it on the Bank of England. The Clearing-house acts precisely as a player at cards, who puts down what each man wins or loses on each game. No money passes all the evening; at the end of the playing each man pays or receives the balance which he has lost or won. At the Clearing-house not a sovereign passes, yet a hundred millions of pounds and more are paid and received every week. The debts and payments are settled simply by new items entered in new lines in all the banking books of all the banks. Is this dealing in money, when no money is touched? Is it anything more than machinery for creating and sweeping away debts? But let us proceed further. After the farmer's cheque has been received by Smiths, a borrower, who wishes to buy cotton, comes in, and asks for a loan of Smiths, his

bankers. They bid him go and buy £700 of cotton, and pay for it by drawing a cheque on Smiths', which is lodged with the cotton-dealer's banker. This second cheque is then sent by Glyn to the Clearing-house, which meets the cheque of £1,000 which Glyn has to the farmer; Glyn, if no other cheque turns up, has to pay the difference of £300; he does by a cheque on the Bank of England. The whole banking transaction is ended. What has happened? First, not a shilling has been paid. Secondly, the farmer has enabled his Smiths to buy; his power to buy they have transferred to a cotton buyer. Thirdly, corn has been exchanged for cotton; the remaining £300 has been transferred to Smiths' account at the Bank of England. Smiths do not lend the whole of the farmer's cheque, £1,000, to the cotton buyer for they know that he will buy things which he wants, and they reserve £300 for these purposes. Thus we see the essence of banking is machinery for exchanging goods. The goods are chased pay for each other by means of paper registered in ledgers. Thus banking is a magnificent tool for buying and selling the work fully, yet, even reckoning notes it saves the necessity of buying and selling £97 of currency. Trade thus gains enormous simplicity and cheapness.

But here the intricacy and danger lie in present themselves. The banker has lent purchasing power belonging to the farmer, whom he has found a borrower in the merchant. But the farmer retains the power of demanding his £700 when he pleases, the cotton merchant may have borrowed on three months, or may have failed, and then to repay his loan. These uncertainties exist. They call upon the banker to know the habits of his depositors, and the business traders to whom he lends what does not harm him. These examinations cannot be made with perfect accuracy; and the bank may fall in some day. Hence arises the necessity of a reserve—that is, a sum to be retained by the bank, beyond what it lends, to guard against contingencies. This reserve, being the difference between the banker's deposits and his loans, will necessarily take the form of cash, notes, or securities. That reserve will vary according to the vicissitudes of business; its fitting amount depends, as a rule, on the judgment of the banker according to the signs of the commercial world. The danger of the bank coming to a standstill is never absolutely absent; often it may be comfortably near. The banker's profit is a charge on the loans he grants, called interest. When danger threatens, he raises this rate of interest, which diminishes borrowing; many who have previously borrowed must repay their loans. The moral which I teach is plainly this—that he should watch and study what is going on in business around him; how far it is safely conducting earning profits; what is the commercial position of his own and other countries; what is the state of the world; what is the position of particular trades; what is the position of particular trades; what risk there may be of

erate a panic and create a run of on banks for the repayment of their. This is the law of right and safe banking in which the thoughts and study of should live. By such vigilance banking is rational. Such a banker in America, crisis of 1873, would have seen that the people were rapidly involving themselves in their excessive construction of fixed out on some 30,000 miles of new rail- would have known that labourers were food and clothing, coals prodigiously making iron and machinery, and that on of all this wealth thus destroyed effected by the railways under twenty ars. The nation must be poor, and and commercial houses failed, and what they had borrowed from banks, banking might have prevented the s, and its effect on the whole com- l.

ccounter, face to face, the most start- astonishing intellectual phenomenon world. What commercial profession has tion for intelligence, for ability, for the range and intricacies of business. banker? Yet that great profession a delusion, an ignorance of the nature s, of what it really is, unknown to any of trade. It would be most pre- und unbecoming in me to use such

I stood alone; but what I have years, I have had the advantage of own to the very dregs before the banker of the very highest eminence, nor of the Bank of England, Mr. as Gibbs. We had a long corre- rich Mr. Gibbs first printed at the land, and then allowed me to publish dix to my last book, "Chapters on litical Economy." The result was agreement on the great point at issue. I will allow me to repeat to you a the question, as stated in "Fraser's of May, 1880. I could not state it or more fully:—

rs find it hard to exercise such a cool and judgment on the operations of their hen they are men. They encounter keen hey can be carried away by the impulses the prospects look bright: the rise of r stimulating: and then calm reason is d. Nevertheless the banking community without the instinct of self-preservation, sought for a rule which should reveal the trade at the time, and enable them to rking with safety. But, unfortunately, upon a purely mechanical rule, a rule of te of common sense; but it lay so close so easy and so natural, and could be most ordinary brains. They bethought he reserve of gold, and a banking fact founded upon it so workable. London keep the substance of their reserves in ls. They have accounts at the Bank of which they store up their reserves, to never they please. Here is the grand ve of the nation, the supply of erve all banks from the danger of money and not having it. The salvation depended upon it. It must be care-

fully watched and nursed. If the reserve rises, let loans be freely made and upon lower charges; if the reserve diminishes, let every banker be on the alert. The Bank of England must then raise its rate of lending, and that rate must be the supreme law in every banking parlour. The reserve of the private Bank of England has thus become the king of all bankers. The doctrine has penetrated into every City article of every journal on every day throughout all England, and from England throughout the world. The law is treated as being as certain as the law of gravity. The movements of the gold are recorded as carefully every day for ascertaining the banking weather as the move- ments of the barometer are published for announcing whether rain or sunshine is approaching. One money market was established for the whole country—the money market of the Bank of England—the other bankers only followed suit. They lent and fixed their interest as the Bank of England directed."

Thus this unhappy absurdity overspread the nation. Its simple rule could be carried out daily with clever comments by every writer of City articles. The common mind could note its mechanics. Then it was very profitable for bankers. The bank rate brought an imperative excuse for levy- ing a tax on all traders, and for an increase of the rate of discount as the reserve fell. It could always be pleaded that they were making the bank safe. It seemed to be an undeniable truth, that every bank which could not pay gold when de- manded must become bankrupt.

In answer to this last plea, let us ask categori- cally, "When does this danger present itself?" Not when business is sound, and no mercantile failures are thought of, even though large sums of gold may have left the reserve. But when the panic has set in, and no one knows what bank may be broken during the day, or what great firm stopped before evening, then is the hour when the strong reserve is most sorely needed, and ought to be most resolutely provided. But what did the Directors of the Bank of England think of their own principle—the avowed governor of their practice—in the greatest of crises, in May, 1866? Did they hug every bag of sovereigns paid in to them, and lock it up in their reserve? They did the very con- trary; they lent it out again as fast as they could; and thus, by their own voluntary action—aye, and with the applause of the Bagehots, and the great oracles of currency—they increased their loans from 18½ millions in April to 33½ millions in May, and emptied their reserve from 6½ millions to ½—to less than 1 million; ½ millions of gold, with 33 millions of loans voluntarily given. They then showed, with the greatest plainness, that they had no belief in the necessity of keeping up a great gold reserve, even in the hour of danger. They treated it with contempt by wilfully lending away in the day of peril for mercantile firms almost every sovereign they could lay their hands upon. They knew perfectly well, in the very teeth of the doctrine preached by themselves, the whole City, and every economical journal—that the public, as in 1825, would have been perfectly satisfied with payments in their own bank-notes, under the liberty of issue given by suspension. There was no fear anywhere of the goodness of these notes. With what feelings must any thinking man, any man of common understanding, read those pitiful daily announce- ments, with their corresponding comments, of a few hundreds of thousands, or even millions,

leaving the cellars of the Bank of England, as if they were anything more than ordinary variations of trade?

The natural action of money is never thought of by the holders of such ideas. Large quantities of money frequently leave the Bank amid profound tranquillity of trade. For what reason? Sometimes because the nation requires more money for currency, as in summer, with its harvestings and travellings, or oftener to pay for an excess of goods imported, or investments made abroad. But what harm is there in all this? Why should it be markedly chronicled as a grave fact, that five millions of gold have been sent to America to pay for sudden purchases of corn required for food? "No harm!" answers Mr. Hucks Gibbs. Money is made for the very purpose of passing from hand to hand, according to the purchases of the day. These five millions are sure to leave America again; they can do her no good in any other way. Her currency was full for the work required before they arrived. Is every trader in England to be warned by every city article, that out of a reserve which amounts to some 45 per cent. of the total liabilities of the bank, a few millions have departed to make purchases abroad? Is there danger, is there bankruptcy, in buying useful goods with gold locked up in vaults? It is lamentable to hear the language used about such events in banking and newspaper regions. Is it not the function of all currency to run? What if by such events the bank's reserve is to fall down to four millions of gold? Is every merchant to tremble in his counting house, every dealer in every exchange? Was anyone frightened about the bank's stopping in 1866, when it had not one million of sovereigns in its possession?

In conclusion, may I venture to say a few more words to you on a subject of extreme importance—the Monetary Conference, which is now sitting at Paris, to promote the universal acceptance of bi-metallism. I will not say, with the eminent economist, M. Leroy-Beaulieu, that this conference is "a gigantic hoax;" but I do not hesitate to declare in the plainest language that this meeting has for its distinct object the making of bad money—false and unreal money—for the whole world. Even one of the advocates of this new system, President Barnard, of Columbia College, has excellently stated that "the real money of the world is bullion;" as has been shown above, the sovereign does its work as the tool of exchange by its worth as a piece of metal—by its value as created by its cost of production.

Now, what is bi-metallism? It is most necessary to have a very clear and definite conception of the meaning of the word, if we are to judge correctly the kind of money it denotes. It is not the mere using by a country of two metals as the tools of its buying and selling. England employs gold and silver coins; but she knows nothing of bi-metallism, and it is to be hoped that she never will. England's money is gold. Her shillings are merely tokens, counters. The definition of a shilling is the twentieth part of a sovereign; the definition of a sovereign is so much weight of gold. The man who buys a ton of coals with a sovereign gives value for value; he who buys a cotton handkerchief with a shilling does not give as much silver as the handkerchief is worth. He gets the handkerchief because with 20 shillings the

seller can get a sovereign, and thus he is real with gold. The shilling counters act like they mean and are twentieths of a sovereign. They work no harm, because they can more than 40 shillings worth of debt, and are not more of them allowed to be in circulation than are sufficient to do the work of small.

Bi-metallism is a wholly different affair. The essence is this—that a debtor must accept payment either of the two metals, in the fixed ratios which the law assigns to them towards each other. England would be bi-metallic if she were passed authorising any debt to be paid in shillings, and any quantity of silver to be taken in payment of shillings. But what would be the result even as matters now stand? Everyone would know what he had nominally bought with sovereigns worth less than 20 to the pound, but he could pay with 20, and probably have profit with his sovereign. He pockets four shillings at the expense of his creditor. The ultimate result would be, that silver would be bought at a premium, and gold to be coined into shillings, which would give every debtor four shillings profit on a pound debt paid. Sovereigns would then leave the country, and goods would be priced in shillings, with the addition of more shillings to the price. The result of debts with foreign countries would be most embarrassing, and accompanied by loss to many; but time fails to enter upon this.

But the mischief is far from ending here when a nation, as England, has only gold money, the uncertainty and greatness of loss even now occasion people anxiety about the payment of debts. We all know the uneasiness created by the presumed devaluation of the value of gold. Prices were held to the value of gold. Prices were held to for all articles, and those whose income depended on dividends, whether of Consols or otherwise, thought themselves painfully poorer. The danger was bad enough with one metal for exchange; it would be increased manifold by the employment of two metals, available at the option of the debtor for the payment of his debt. The bi-metallic shilling might be rated as equal to the sovereign; but how, if silver is extra cheaply from the mines, and the miner is willing to give 30 shillings for a sovereign of gold? And these variations might be rapid, and enormous losses might be incurred by creditors, in what they received as their payment in England and abroad. The misery in the cost of gold alone would be bad enough, and the changing worths of two metals authorised to pay debts in fixed proportions could describe the sufferings they might undergo. Would not the adoption of two standards of value be called, by the choice of either of them by debtors, be indeed a creation of doubt and anxiety?

The bi-metallists are aware of this danger of the ruin it would bring on the money—of any country; but they believe that they have discovered a remedy for the evil. The value of the metals at present may be as 1 oz. of gold being equal to 18 ounces of silver. These quantities transferred in exchange would yield equal worth of metal to each end. It might have been expected that the bi-metallists would have taken their start from this

ty of 1 to 15; but no; from motives apparently very easily intelligible to some of their number, they assume the proportion of 1 to 15½, giving an excessive, unnatural, unreal, and artificial value to silver. They then propose that the nations shall decree that gold and silver in that proportion shall be issued, and shall be payable for all debts. If the creditor was given the option, he would reject the deficient quantity contained in 15½ of silver for his debt in gold. They do not deny that he would be obliged, but they think they have found the way of limiting the coinage of silver so as to pass for what they please, and thus the gold and silver coins to be exchanged for their own selected proportion of value. If the supply of all the silver mines could be created, it might be possible to create such a system. Silver might be made scarce in comparison with gold for it, and thus its value might be raised at the required proportion of 15½. But monopoly is a pure delusion. In any country, many silver-producing nations would come out, and they would ruin the projected system. They would make silver coins for all the world, the United States, forged, but all of full silver would introduce them easily into the monetary system, deluge them with these coins, with no profit to themselves. Thus silver would become the sole coinage of these countries, and gold would disappear. The law of all money then asserts itself—prices would all rise—gold would form that money, and debtors, creditors, and traders of every kind would be driven to the extreme uncertainties of the value of silver. The relation of debtor and creditor would become intolerable; and gold ultimately be restored to its supremacy as

while, another result would be sure to follow. All goods would have two prices—one in gold and one in silver; and this last would vary with the fluctuations of the worth of the metal. A possible motive can be assigned for subjecting nations to the folly of selecting such

as the other side, it must be admitted that it is important to retain the use of silver for some of the world. To banish silver altogether, even were it possible, would lead to a great moment of the worth of gold, to a scarcity in comparison with the work which it would do, and many inconveniences would arise. It is only one principle, as far as I know, on the joint bi-metallic use of silver, in connection with gold, can be carried out successfully, suggested by Mr. Clarendon Daniell, in his last. "Gold in the East," and further dealt in the *Westminster Review* of January. He proposes that gold should always be standard, and remain unchanged; but that there should also be a complete legal coin for all that in such proportion to gold as shall be fixed from time to time by a public authority according as its intrinsic value, its metallic value, shall suffer fluctuations. In this manner silver will always receive in silver the gold of its debt, and silver, under such conditions, will be employed without mischief to perform the work of currency.

## DISCUSSION.

The Chairman said they had had a most interesting and instructive paper on a subject which the Society had not discussed much recently, and he thought they would all agree that the Professor deserved their sincere thanks. For his own part, nothing would please him better than to be able to sit under Professor Price in the theatre at Oxford, and learn more thoroughly the principles which he had enunciated. The author had very fully treated of the value of money as a tool for the purpose of exchange, and in the main principles enunciated he entirely agreed with him. Money, after all, was simply a convenient method by which to regulate exchanges. It had a recognised value by which we could regulate exchanges and balance accounts. Trade was simply a system of barter regulated by the exchange of money in order to effect the balance at the end of the year. If that was the case, they arrived at the principles so ably stated in the paper. There were, however, one or two points on which he was not prepared to go entirely with the author. The case of a hat and a sovereign had been mentioned, but he must say he thought a sovereign had an intrinsic value greater than a hat, though the cost of producing it might perhaps be rather less of the two. There was a great deal of labour involved in the various processes of manufacture of the hat, whilst the gold was found in the ground, though of course, it required a certain amount of labour to extract it. It appeared to him there was as much labour required to find a diamond, which was worth several times as much as the gold. Then, again, gold had a certain difference in value. Some years ago he visited Australia, and bought some gold there, which he sold in London at £4 2s. 6d. per ounce, though the standard value, as regulated by the Act of 1844, was £3 17s. 10½d. He got this enhanced price in consequence of what was called the betterness of the gold, and that gold naturally would be valued higher than standard gold; yet it was as easy to produce as gold of lower value. It therefore appeared to him that gold had a value over and above that created by the simple production. This, however, was a point which might be open to question; and he was not prepared to discuss it fully. With regard to bi-metallicism, it appeared to him that if, by any means, they could prevail upon the Government of India to introduce a gold standard, instead of a silver one, the effect would be to very much improve the trading relations of this country. It would lead to a considerable absorption of gold in India, and cause the purchasing power of gold to rise here. Silver would be simply used for a token coinage, and for useful manufactures.

Prof. Price said, with regard to the observations of the Chairman, that it was quite true that the finances of India had been very disastrously affected by the fall in the value of silver, because a large proportion of the income of India was fixed, a hundred years ago, at so many hundred silver rupees; and instead of being worth 2s., they were now only worth 1s. 6d. Therefore the Government had to buy at much dearer rates, while its income, which could not be altered, was worth very much less. He knew only one principle on which the object aimed at could be attained, and it was the one referred to at the close of the paper, recommended by Mr. C. Daniell. Gold had a greater intrinsic value than copper, simply because a much greater amount of the latter was produced with a given quantity of labour.

Mr. Proudeston remarked that in ancient times, not only had skins a fictitious value, but a fluctuating value, according to size and quality, and, therefore, certain ancient American and Eastern tribes adopted the plan of cutting a piece out of the skin, which became a token. That he believed was the earliest known instance of a

token being used in lieu of the thing itself. Again, letters of credit and bills of exchange were by no means modern; they existed in China and the far East in very ancient times; the necessity for not keeping large amounts of capital locked up was recognised nearly twenty centuries ago. He had seen some very ancient bills of exchange in the East, which had passed from hand to hand as money. There was also in ancient times another standard of value, viz., a measure of rice, the standard measure being an average days' ration for an adult. Of course this somewhat fluctuated as there was a scarcity or plenty, but in times of plenty it was stored up against times of scarcity. Besides this, there was an arbitrary standard, which was supposed to represent the value of rice in metal, and it was said that so many days' rations of rice equalled a certain standard of gold, which was the metal *par excellence*. Within his own experience, the Carolus dollar in China was worth from 60 to 70 per cent. more than its actual value in silver during a certain period, and other well-known coins had a value far above their intrinsic value as metal. He might also mention that a paper currency had been issued on the basis of the rice standard, and he once had a large number of specimens, which were now in the possession of the Emperor of Austria, of this old paper currency; the different notes or tickets representing one day's ration, one and a-half days', five, or ten days' rations of rice, and these passed from hand to hand. It was a curious fact, that when the English established a mint in Hong Kong, they were obliged to close it, most of the *employés* being sent to Japan, because the Chinese would not adopt the currency, and he believed most of the gold and silver coins went to adorn the jackets of young swells in Canton.

Mr. Robert Manuel said Mr. Price had described the object of the Conference now sitting in Paris as an attempt to foist silver money on the world at a fictitious value. He must admit that, when its actual value was in the ratio of 18 to 1 of gold, and they were trying to get it into circulation at 15½ to 1, that course could not be justified; but was not the ratio of 15½ to 1 a fair one, taking the old value of the silver? And they had to consider why silver had fallen in value. Was it not, to a great extent, due to the action of the German Government, who, some ten years ago, finding themselves rather flush, thought they would demonetise their silver and adopt a gold standard. They were, perhaps, wise in doing so, but the result was to flood the market with silver, and it was well known to those who dealt in bullion that the German Government had now in their coffers silver which they were waiting to sell when opportunity offered, and this was always a bugbear in the silver market, and kept down the price. He would not urge that our Government should adopt bi-metallism, because we got on very well with gold; but it must be borne in mind that, if the suggestion of a gold currency in India were adopted, it would make such an enormous demand on the stock of gold—which was not by any means too large for the requirements of western civilisation—that it would appreciate to a serious extent the value of the metal. Again, the habits of the people of India were different to those of the west; there was a tendency amongst Hindoos to hoard, and if they had a gold currency, they would hoard gold as they did silver; and being smaller in bulk, the effect would perhaps be worse. He would ask whether it would not be better for the world in general if those nations which were willing to act on the bi-metallic principle fixed on some ratio—if 15½ was not fair, say 16 or 16½ to 1, or something approaching the actual ratio, and by that means re-introduce silver into the currency, which would then force up silver to something like its old value. We should have our one gold standard, and in India there would be a silver standard, but the

Government would save the loss on the exchange now amounted to about three millions a year.

Mr. Wm. Botly said the last speaker had principles on which he should have addressed himself, and he would merely add that, having Colonel Smith's paper on bi-metallism, he inclined to the opinion that if silver were made gold, it might be a great advantage to this the legal tender of silver were raised from would be a great convenience, and would prejudice which was now felt against it. To India, he feared it would be almost to adopt a gold standard with advantage; but might be made of varying weight. It was possible, in a country like India, to do better silver in value.

Mr. Hedley Millyard said the Professor of gold purchased by reason of its cost of production if that were so, gold must be taken as a commodity in exactly the same way as a you might substitute for gold in that bale of cotton piece goods. Then it came that a bale of cotton bought by virtue of production; but it had been proved as *pari ratione*, that its sale was simply required demand for it. The question of the price of gold cropped up again when the Professor discussed whether gold had of late years become dearer. It would seem that the only data determining the purchasing power of primeval distribution, which it was impossible to determine deductively. They held which they could treat the question in whether gold had been dearer or was. Whether the gold discoveries of late years to neutralise any deficiency which came about in the currencies of the world, the question of wear and tear, was a question to determine deductively. The Professor at the alarm which was felt in mercantile circles the question of whether our imports or exports, but he did not think the question settled in that way. Some years ago, for instance when the Bank of England saved by borrowing two millions of the Bank of France, and that clearly showed were some specific phenomena by which to gauge this question. It showed that bullion might go on unperceived, and known in the event of a commercial case clearly we were not aware of the Bank of England, and it was very probable the proposition were true if we took mercantile statistics. Take the case of the position of that trade with America. He said that the fact that our imports exceeded was beneficial to this country, inasmuch as for protective purposes, our goods were produced from America altogether.

Mr. M. S. S. Dignall thought the imperious had been rather overlooked in considering you took hats, umbrellas, or shoes, and so a closet for a hundred years, they would worthless, probably they would be no whereas a sovereign would be as good as coined. The subject of bi-metallism was he had much studied, but it struck him that sovereigns with shillings, there would more wear and tear in the latter representation value, and therefore there must be some difference in the value of the two metals for purposes of that point of view alone. With regard could be no doubt that many men there held the depreciation in silver, owing to their contracts were made in that metal; they all deplored, but he did not see how

With regard to the Chairman's remarks on gold being worth £4 2s. 6d. an ounce, account of its greater purity: the standard is £3 17s. 10½d., and if gold were found in it, clearly the owner was entitled to the £4 did not readily see how two distinct standards could exist in any fixed ratio to each other, of time together.

He remarked that Professor Price seemed by having a gold standard they were not to inconvenience of fluctuation in the value; suppose the commercial value of gold changed by some discovery which should produce on the one hand, or, on the other, make it more valuable, the value of debts old would then change accordingly. If wheat, or cotton, or anything else as the standard would be always exposed to the same old happened to be a little more staple, he believed the use of it as a standard of value, and that there was little more in that in it. It was said that silver coins were used, but he thought it would be almost impossible for a powerful Government, to substitute silver metal. The silver shilling might not be the value it was supposed to represent, reached very closely to such representation. On the question of exports and imports, he said that from the Professor, when he said we were alarmed because our imports were in excess, it showed we were getting richer. The

what was meant by getting richer? we were now receiving the interest which was invested in New Zealand, and other places. But what was the process capital was invested there? Was it not a greatly exceeding the imports for a time? We sent out steam-engines and other things, as investments, from which we received the interest, and that was the rich we got rich. But now, when we have more imports, the question was what they were, whether we were getting richer, and whether or not we were spending more which was invested abroad. Suppose that this had very large sums in American securities, American war; most of it was sent out in merchandise; and were they not, at that time, richer? Then, during the time of bad harvest, we received a very large proportion of our American, and consumed it, it seemed to us at the end we might have eaten up, in the shape of what we had invested in former times, when it was sent to America; and that seemed to him a sign of being poorer, and not richer. At any rate, the preference of those who thought that an excess of imports was not a healthy state of things.

He having proposed a vote of thanks to the speaker, which was carried unanimously,

Mr. Price, in reply, said he quite agreed with the gentlemen who desired that both silver and gold should be used. The supply of gold was for all the purposes of currency, and the use of silver it would acquire an artificial value. All he meant to say was that he did not see any other way in which the two metals could be used together than that of one being taken as the standard, and that the other be adapted to it, in the ratio of production. Mr. Daniell's idea of a small stock of gold should be used in the case of a large quantity of silver should be used, but that the payment of debts in silver should be made in the proportion which silver bore to gold to token coinage, in Austria and elsewhere, and even fourpenny notes, and perfectly well, except that they got dirty

and torn, and were hard to distinguish. A hard token like silver had a great advantage from its durability. He could not answer Mr. Hillyard's questions without going into the whole subject of banking, which was too large a one to enter upon then. One of the reasons why a large supply of coin was not wanted in England was that our machinery of payment by means of cheques, and the Clearing-house system, was so perfect; but all this was arranged on the basis of a gold standard. With regard to exports and imports, of course they might have various motives, but those who made investments abroad were not the people who talked about exports and imports, it was always the traders, and as a matter of trade, the advantage was in the imports. Debts might be paid this year or next, or in ten years time, but the exchange was always of goods. If England made foreign loans, it was always in goods; she had no superabundance of gold to send abroad. If she had spare goods, it might be a good investment to send that extra store got by saving and productive consumption abroad as exports, with the intention of the equivalent not coming back, but that was not the language of the mercantile world to which he was alluding. Imports might be like American wheat, which supplies the place of a great destruction of wealth here. There was no doubt we had had very defective harvests, and the alternative was either to buy corn abroad or starve. Of course he did not mean to say that the buying American corn under such circumstances was a sign of prosperity, but it was an excellent purchase nevertheless, and the importation was a source of wealth, because it kept the nation alive. The loss was not in the importation, but with the loss of the harvest. But that was not the question with which he was dealing. The principle always remained the same; trade was an exchange of goods and nothing else whatever.

## GENERAL NOTES.

**The Commerce of London.**—Sir John Lubbock has communicated to the papers the following account of the operations of the London Bankers' Clearing-house for the year ended April 30:—

"15, Lombard-street, May 2.

"Sir,—I beg to forward you the subjoined statistics, showing the working of the Bankers' Clearing-house for the year ended on the 30th of April, 1881, which is the 14th during which these statistics have been collected. The total amounts for the 14 years have been—

	Total for the Year.	On Fourths of the Month.	On Stock Exchange Account Days.	On Consols Settling Days.
	£	£	£	£
1867-1868 .....	3,257,411,000	147,113,000	444,443,000	132,283,000
1868-1869 .....	3,584,039,000	161,281,000	550,622,000	142,270,000
1869-1870 .....	3,720,623,000	168,623,000	591,703,000	148,822,000
1870-1871 .....	4,018,464,000	188,517,000	635,946,000	169,141,000
1871-1872 .....	5,359,722,000	229,620,000	942,446,000	233,843,000
1872-1873 .....	6,003,335,000	265,905,000	1,082,474,000	248,561,000
1873-1874 .....	5,003,691,000	272,811,000	970,945,000	260,072,000
1874-1875 .....	6,013,290,000	255,950,000	1,078,545,000	260,338,000
1875-1876 .....	5,407,243,000	240,807,000	962,595,000	242,245,000
1876-1877 .....	4,873,001,000	231,630,000	718,703,000	223,756,000
1877-1878 .....	5,066,533,000	224,190,000	745,685,000	213,385,000
1878-1879 .....	4,985,691,000	212,241,000	811,072,000	221,264,000
1879-1880 .....	5,265,976,000	314,477,000	965,533,000	253,143,000
1880-1881 .....	5,909,089,000	240,822,000	1,205,197,000	266,579,000

The total amount of bills, cheques, &c., paid at the Clearing-house during the year ended April 30, 1881, shows an increase of £644,018,000 as contrasted with 1880. The payments on Stock Exchange account days form a sum of £1,205,197,000, being an increase of £289,664,000 as compared with 1880. The payments on Consols account days for the same period have amounted to £266,579,000, giving

an increase of £32,436,000, as against 1880. The amounts passing through on the 4th of the month, for 1881, have amounted to £240,822,000, showing an increase of £22,845,000, as compared with 1880. At the same time I may observe that four Consols settling days fell on 4th of the month, while there only happened one last year. This would account for a considerable portion of the increase. Messrs. Derbyshire and Pocock, the inspectors of the Clearing-house, have been good enough to prepare for me the above figures, which will, I think, be interesting to many of your readers.—I am, sir, your obedient servant,  
"JOHN LUBBOCK, Hon. Sec. London Bankers."

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MAY 11.—"The Manufacture of Glass for Decorative Purposes." By H. J. POWELL (Whitefriars Glass Works).

MAY 18.—"The Electrical Railway, and the Transmission of Power by Electricity." By ALEXANDER SIEMENS. DR. SIEMENS, F.R.S., will preside.

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 10.—"Trade Relations between Great Britain and her Dependencies." By WILLIAM WESTGARTH. Lieut.-Colonel Sir ROBERT R. TORRENS, K.C.M.G., will preside.

### APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MAY 12.—"Recent Progress in the Manufacture and Applications of Steel." By Prof. A. K. HUNTINGTON.

MAY 26.—"Telegraphic Photography." By SHELFORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

### INDIAN SECTION.

Friday evenings, at eight o'clock:—

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B. Sir RUTHERFORD ALCOCK, K.C.B., will preside.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fourth Course will be on "The Art of Lace-making," by ALAN S. COLE. Four Lectures.

*Syllabus of the Course.*

#### LECTURE IV.—MAY 9.

*Resumé* as to styles of design in hand-made lace. Traditional patterns. Sketch of the development of inventions for knitting and weaving threads to imitate lace. Differences between machine and hand-made laces. Modern hand-made laces at Burano, Bruges, Honiton, &c.

This course will be illustrated by specimens of lace. Diagrams and photographs enlarged will be shown by means of the lantern and oxyhydrogen light.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 9TH...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Alan S. Cole, "The Art of Lace-making." (Lecture IV.) Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting. Royal Geographical, University of London, Burlington-gardens, W., 8½ p.m. Mr. Edward Whymper, "A Journey amongst the Great Andes of the Equator."

British Architects, 9, Conduit-street, W., 8 General Meeting.

TUESDAY, MAY 10TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Mr. William Westgarth, "Trade Relations between Great Britain and her Dependencies." Royal Institution, Albemarle-street, W., 8 p.m. Dewar, "The Non-Metallic Elements." Medical and Chirurgical, 53, Berners-street, W., 8½ p.m. Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. John I. Thornycroft, "Boats and Light Yachts for High-Speed Motion."

Photographic, 5A, Pall-mall East, S.W., 8½ p.m. Anthropological Institute, 4, St. Martin's-street, W., 8 p.m. 1. Prof. G. Dancer Thane, "Some Notes on the Geology of the Naga Hills." 2. Lieut.-Col. R. G. Woodthorpe, "The Naga Hills."

Royal Colonial, Grosvenor Gallery, Library, Bond-street, W., 8 p.m. Sir Charles N. Prince, "Principle which ought to regulate the delimitation of the Political and Municipal Boundaries of the Colonies."

Royal Horticultural, South Kensington, 8 p.m.

WEDNESDAY, MAY 11TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. H. J. Powell, "The Manufacture of Glass for Decorative Purposes." Geological, Burlington-house, W., 8 p.m. W. Davis, "Notes on the Fish-remains of the Aust, near Bristol, with the Descriptions of New Genera and Species." 2. Rev. J. H. M. "Certain Quartzite and Sandstone Fossils in the Drift in Warwickshire, and identify with the true Lower-Silurian." 3. Mr. Francis D. Long, "On the Diastopora and Stomatopora, from the Devonian Limestone." 4. Prof. W. J. Sollas, "On the Pleistocene (P. Conybeare) from the Charnmouth."

Microscopical, King's College, W.C., 8 p.m. Royal Literary Fund, 10, John-street, W., 3 p.m.

Ascham, 18, Baker-street, W. Prof. J. H. M. "The Place of English in a Liberal Education."

THURSDAY, MAY 12TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Applied Chemistry Section.) Professor A. K. Huntington, "Recent Progress in the Manufacture and Applications of Steel." Royal, Burlington-house, W., 8½ p.m. Antiquaries, Burlington-house, W., 8½ p.m. Society for the Encouragement of Fine Arts, 1, Pall-mall East, W., 8 p.m. Dr. Phené, "Art in the Royal Institution, Albemarle-street, W. Tyndall, "Paramagnetism and Diamagnetism III."

Inventors' Institute, 4, St. Martin's-place. Royal Society Club, Willis's-rooms, St. James's, 6 p.m.

Mathematical, 22, Albemarle-street, W., 8 p.m. W. R. W. Roberts, "Note on the Curve of the Tangent Line to the Curve of Intersections of Quadrics." 2. Mr. E. Carmichael, "So the 15 School-girl Problem." 3. Mr. C. "Note on Ptolemy's Theorem." 4. "Algebraical Notes." 5. Rev. T. J. Summation of Certain Hypergeometric Series.

FRIDAY, MAY 13TH...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Indian Section.) General Monthly Meeting. Mr. F. Phayre, "Burmah."

Royal United Service Institution, Whitehall, 9 p.m. Captain J. R. Colomb, "Naval Intelligence and Protection of Commerce in War."

Royal Institution, Albemarle-street, W., 8 p.m. Meeting. 9 p.m. Mr. F. Galton, "The Vision."

Astronomical, Burlington-house, W., 8 p.m. Folk-Lore, 22, Albemarle-street, W., 8½ p.m. Wheatley, "The Superstitions of the People of the County of Devon."

Clinical, 53, Berners-street, W., 8½ p.m. New Shakespeare, University College, W.C., 8 p.m. J. Kirkman, "The Suicides in Shakespeare's Plays." 2. Mr. F. J. Furnivall, "The Cruces early Comedies."

National Health Society, 23, Hertford-street, W., 8 p.m. (Drawing-room Lectures.) Mr. H. P. Education of the Eye."

SATURDAY, MAY 14TH...Physical, Science Schools, S.W., 3 p.m. Prof. H. A. Rowland, "Electric Absorption in Crystals." Royal Botanic, Inner-circle, Regent's-park, 8 p.m. Geologists' Association, University College, W.C., 8 p.m. Association to Croydon.

Royal Institution, Albemarle-street, W., 8 p.m. Henry Morley, "Scotland's Part in English History." (Lecture III.)

## OF THE SOCIETY OF ARTS.

No. 1,486. Vol. XXIX.

RIDAY, MAY 13, 1881.

as for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W. C.

## NOTICES.

## CONVERSAZIONE.

y's *Conversazione* is fixed to take place  
Kensington Museum (by permission  
s of the Committee of Council on  
on Thursday, June 2nd. The cards of  
ill be issued shortly.

## CANTOR LECTURES.

and concluding lecture of the fourth  
"The Art of Lace-making," was  
ALAN S. COLE, on Monday, 9th inst.  
gave a *resumé* of his subject, and  
the variety of styles of design in hand-  
He then described the development of  
or knitting and weaving threads to  
and showed the distinctive differences  
shine and hand-made lace, by means  
ed photographs shown on the screen.  
d with a notice of the modern hand-  
f Burano, Bruges, Honiton, &c.  
specimens of lace, kindly lent by Mrs.  
ison, Messrs. Hayward, and Messrs.  
James, were exhibited on the table.  
thanks to Mr. Cole, for his interesting  
ctures, was proposed, and carried

## FURNITURE EXHIBITION.

ations for the Exhibition of Works of  
o Furniture at the Royal Albert Hall  
ely completed. The Exhibition will  
n Monday, May 16th, at the same  
General Art Exhibition at the Albert

## PLANT LABELS.

In response to the offer of a medal and prize of  
£5, for the best labels for plants, labels have been  
received from 120 competitors.

## PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held  
by Dr. Hullah, the Society's Examiner, at the  
House of the Society of Arts, 18, John-street,  
Adelphi, W.C., during the week commencing on  
the 4th July, 1881.

## HONOURS.

The Examination in Honours will consist of  
three sections, viz., a paper to be worked, an  
examination similar in form to the practical  
examination for a First and Second-class, and a  
*viva-voce* examination.

## FIRST AND SECOND-CLASS.

*Vocal.*

Candidates for a First or Second-class Certificate  
in Vocal Music will be required—

[1.] To sing a solo, or to take part with another  
candidate in a duet, already studied.

[2.] A key-note being sounded and named by  
the Examiner, the candidate to name sounds or  
intervals, or successions of sounds or intervals,  
played or sung by the Examiner.

[3.] To sing or sol-fa at sight passages selected  
generally from classical music.

*Instrumental.*

Candidates for a First or Second-class Certificate  
in Instrumental Music will be required—

[1.] To play a short piece, or a portion of a  
larger work, already studied.

[2.] A key-note being sounded and named by  
the Examiner, the candidate to name sounds or  
intervals, played by the Examiner.

[3.] To play a piece or portion of a piece at  
sight.

The fee is 10s. for the Honours (including both  
vocal and instrumental Examination), and 5s. for  
the First or Second-class (vocal or instrumental)  
Examination. If vocal as well as instrumenta  
music, or two separate instruments, be taken by  
the same candidate for the First or Second-class  
Certificate, a fee of 7s. 6d. must be paid.

The examination of each candidate will be  
private; no one but the Examiner and the accom-  
panyist being present, unless it be a member of  
of the Society of Arts' Committee.

No list of Candidates will be published.

Full particulars can be obtained on application  
to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

### FOREIGN AND COLONIAL SECTION.

Tuesday, May 10th, 1881; JAMES A. YOUL, C.M.G., in the chair.

The paper read was—

### TRADE RELATIONS OF THE COLONIES AND THE MOTHER COUNTRY.

By William Westgarth.

#### INTRODUCTORY REMARKS.

In presenting adequately to my audience the great subject I have ventured to take in hand, it will be necessary to begin with a few introductory and explanatory remarks upon the colonial or external parts of our Empire. The importance of that part of the British Dominions cannot be better illustrated than by the fact that it comprises forty distinct societies and governments, whose united public yearly revenues are over 90 millions sterling, with a total yearly trade of 320 millions; that it covers an area of nearly nine millions of square miles, or about one-seventh of the whole land surface of our globe, with a population of 254 millions, or no less than between one-fifth and one-sixth of that of the whole world.

But first let me make here a passing comparison with the illustrious mother of the family, who, indeed, cannot fail to be illustrious, even if she were nothing more than the mother of so great and varied a household. But she has, besides, her own attainments to stand upon. Within an area only 1-75th of that of her family, and a population of between a seventh and an eighth, she now creates, within that comparatively small space of about 120,000 square miles, a yearly public revenue of more than eighty-four millions; and with 633 millions of yearly trading, has nearly twice the amount of the united total trading of all her vast family.

This colonial family is most variously—indeed, picturesquely—constituted, embracing, as it does, very large proportions of other races than our own, a great variety of climate and production, and no small diversity in social and political aspects. I distinguish three leading classes of our outside possessions:—1st, Colonies proper, consisting substantially of societies of our own race. These are, respectively, the North American group, now all, with only the one exception of Newfoundland, comprised in the Canadian Dominion; the Australasian group, and the Cape Colony. All these enjoy a reflex of our civil system of constitutional self-government, subject, of course, to imperial supremacy. 2nd, Dependencies of substantially foreign races, which, as the rule, are not constitutionally governed, that is to say, by popular representation, but by a system of Crown nomination, and, therefore, distinguished as Crown Colonies. Of these, our great leading figure is India; and we have, besides, Ceylon, the Straits Settlements, Mauritius, Natal, the West Indies

generally, Guiana, Honduras, Sierra Leone Coast, and some others. 3rd, Military Colonies as Gibraltar, Malta, Cyprus, Bermuda, Ascension, St. Helena, &c. I might have found yet a class in convict colonies, such as Bermuda continues; but as that is now an expiring class, I have included its remnants in the military. Within only the last forty years, however, the convict system has included, besides British New South Wales (with its offshoot, Van Diemen's Island), Tasmania, and West Australia.

No clear line, however, separates the classes from each other. There is partial representative privilege in some of the Crown Colonies. It might be puzzling in which class we put little St. Helena, although I have given it to the military. Then, again, there are great times disturbing foreign social elements free or constitutional colonies. The native element in Canada is of no politics, but there is a large although happily French element. In Australia again, the English have never raised a political question, the case has been very different in New Zealand, and lastly, in our Cape dominions we have still have, most embarrassing relations with the Dutch and the aboriginal elements.

#### MODE OF TREATING THE SUBJECT.

Our view of the trade relations of our colonies to the mother country would be quite different if we omitted allusions to these political circumstances, connected as they are too important but interminable tariff questions springs up everywhere over the colonies and which claims our attention equal to that of the mother country in regard to trading which it affects or regulates. Therefore, to present my subject in the proper order:—

First, we shall look at the progress of the attainments of the trading between the mother country and the colonies, with a comparison at the foreign trading.

Second, we shall examine some of the features and chief items of all that trading.

Third, we shall consider the trade in regard, mainly, to the relations, complicated difficulties of the tariff question.

Fourth, and lastly, we shall make some reflections on the whole case.

I am aware that this Society excludes controversy from its proceedings; and, properly so, seeing that the great political question of the country may equally meet within the walls, to promote its many national objects. But the large and varied collection, when we have occasion to touch upon part of it, is happily, as you will see, a political one, in the objectionable sense of political parties.

I have yet one further introductory remark. My subject bristles with facts and figures, too common fault of papers of this kind, and weary the memory in that we have carefully tried, and I hope successfully, that fault, while at the same time not to such sufficiency of statistical illustration full justice to my subject, and make it intelligible to my audience.

# GRESS AND PRESENT POSITION OF THE ING BETWEEN THE MOTHER COUNTRY AND COLONIES, AND COMPARISON WITH FOREIGN DING.

## Two Remarkable Features.

glancing over the figures presented by our  
sree, we are at once struck by two different  
remarkable features; one, the largeness of the  
at as compared with that of other countries,  
he other the comparative velocity of the pace  
eace or progress in these later years. In the  
st of our total trade, that is to say, of our  
eet imports and exports, our country is far  
any other country in the world, not  
ing even such advanced commercial countries  
eace and the United States, although their  
ghly organised, industrious, and highly  
ent populations respectively exceed our  
While our total trade for 1880, exclusive of  
ed bullion, reached 633 millions, that of  
for the same year was £332 millions, and  
the United States 317 millions. If to the  
figures of our United Kingdom we add the  
tions of the aggregate colonial trading, we  
to nearly 1,000 millions for the whole  
an amount that makes a very substantial  
sh to the total trading of all the rest of the  
cial world put together.

Other striking feature, that of the accelerated  
s of the later years, is so interesting, more  
ly as it appears to be common to the other  
t nations of the day, that I shall hope to  
eed if I dwell here for a moment upon it.  
ook back only twenty years. Our country's  
now 633 millions, was then but 347  
; that of France, now up to 332 millions,  
n only 167 millions; and that of the United  
now at 317 millions, was then but 143  
.

Although our country now stands com-  
ly so far ahead of any other in the world,  
n be no doubt that if, like Rip van Winkle  
he Atlantic, we were to drop asleep for a  
years, or perhaps even for but the one  
that short space of a nation's life, we  
awake to find that France and the United  
ad both overtaken or surpassed us. By so  
step ahead in this inspiring race is our  
supremacy held.

remarkable acceleration of commercial pace,  
rds our own particular case, appears to  
egun about half a century ago. The  
tion has indeed been of a general as well  
erely commercial nature, and has been  
ble alike also to social, political, and  
ic progress. Our great colonial develop-  
also are mainly within that brief space. In  
anada had but small pretensions compared  
present four millions of colonists, five  
s sterling of yearly revenue, and fifty-five  
s of yearly trade. The wide and expanding  
tlements, now so conspicuous for wool and  
products in the empire's commerce, were  
ndustrially considered at least, an almost  
space, hardly more than geographically  
r to us. Australia was known here as being  
ore to us than the two convict settlements  
'South Wales and Van Diemen's Land (now  
ia); whilst the newest member of the  
New Zealand, contained, colonially speak-

ing, but a handful of adventurers and missionaries,  
the latter of whom in particular, as Sydney  
Smith, in his characteristic way, has humorously  
reminded us, served occasionally as choice  
delicacies on the sideboards of cannibal natives.  
But already, Australasia, with three millions of  
colonists, sixteen millions of yearly revenue, and  
ninety millions of yearly trading, is casting even  
Canadian progress into the shade.

In this remarkable feature of a greatly accelerative  
progress, the colonies generally are stepping ahead  
of, and in some cases—as in the instances given—  
even much more rapidly ahead proportionately  
than the mother country herself. We may have  
some reflections to offer on this portentous con-  
dition and prospect further on. It is portentous,  
but by no means unwelcome or alarming. But  
turning, meanwhile, once more to the home pic-  
ture, we see the acceleration in question fairly  
illustrated by the progressive statistics of our  
shipping. The collective outward and inward  
tonnage for the United Kingdom, exclusive of the  
coasting trade, appears as follows, prior to and  
after 1830, or fifty years ago:—For 1814-16, the  
yearly average was 4·3 millions of tons; for 1820,  
5·3; for 1830, 5·8. Thence, entering the era of  
marked acceleration, we have for 1840, 9·4; for  
1850, 14·5; for 1860, 24·7; for 1870, 36·6; for  
1878, 51·6. In the total trade also we show the  
same remarkable later acceleration; and we have  
that feature in common with France and the  
United States, whose cases have been just alluded  
to; for while our present amount is 633 millions,  
25 years ago it was but 289 millions, or consider-  
ably less than the amount to which either France  
or the States have now attained.

## The Uncertainty of Past Official Trade Records: "Official" and "Real" Values.

Allow me here a few words upon a very im-  
portant, but not much understood, subject,  
namely, the uncertainty, or rather the totally mis-  
leading effect of the system of our earlier official  
trade records, and more especially as to the import  
trade prior to the year 1854. I have pleasure in  
acknowledging that I owe the information I am  
now giving you chiefly to my friend, Mr. Stephen  
Bourne, the able and practised statistician of our  
Customs' department. We are still lingeringly  
familiar with the alternative terms "official" and  
"real" values in our import and export figures;  
for until 1869, when the "official" were given up,  
both used to be presented to us. We may readily  
guess at the meaning of real, but what are  
"official" values? The old or original Custom-  
house practice was to keep the respective values  
unchanged, as they were handed down from past  
years, no matter what change in price had really  
occurred in the interval in the articles imported or  
exported. When a new article appeared in the  
list, its value at the time was recorded, but at that  
value or price it afterwards unchangeably stood.  
In this way we have complete returns dating from  
1699, but returns utterly unreliable, except in a  
comparative way, not as to value, but as to quan-  
tity. Fortunately, a "real" value for the ex-  
ports has come concurrently down to us with the  
"official" value from 1798. A real value was  
then first required for the purposes of a war tax in  
that belligerent time for convoys to merchant

for its steadiness, not only in its, but even in the case of each colony or group. In this respect the more reliable element to us of a very noticeable falling off in our not less abnormal increase in our last five years, whatever it may all it have other than a temporary or primary signification, is entirely a colonial irregularity. It is, however, of sufficient interest to call for some under our fourth and last head. With my remarks, let us proceed to glance at the components of the great trade of our colony. It may be understood that, of the total, rather more than one-fourth, are sent to our own possessions, and the remainder to foreign places.

#### *Country sending to Colonies.*

The most important article in our export trade, in its manifold diversities of origin, is at considerable distance, but still comes, next the varied woollens of linen are, comparatively so. We have further a substantial head of iron and steel products, exclusive of that of the lighter articles and cutlery, is close up to that of the cotton. These three great classes of commodities, namely, cottons, including cottons, including woollen yarn; and iron and steel, constitute the conspicuous export trade. In 1879, they comprised a total of 103 millions out of a total of 192 millions. The cottons were 64 millions, the woollens to 19½ millions, the iron and steel to about the same. Groups of less value are apparel and 8 millions, coal and fuel products 6½ millions, and yarn 6½ millions, and cutlery 3½ millions.

#### *Country sending to Mother Country.*

On the other side, the chief raw materials for our colonies for a number of years have been sugar and wool. Since 1861 we have been prominently conspicuous in Australasia. More recently we have high at business in wheat and other breadstuffs in Australia and New Zealand, as well as from her boundless corn lands of New Zealand. Not less important, perhaps even more so, is the prospect of our animal food, and by some of the advanced scientific stock production now being vigorously pursued in Australia, where ten million head of cattle and millions of sheep are already in wait-

ing for sugar production, in spite of great domestic consumption, seems somewhat early the whole export comes to the 7,347,000 cwt. exported in 1880 to only 7,878,300 in 1876. Wool, however, presents a much more lively, extraordinary, progress. The 127 millions weight exported (also nearly all), in 1862 had risen to 413 millions in 1880, sufficient to furnish a woollen garment for every inhabitant of Europe. The

gold production, on the other hand, after attaining the quite surprising dimensions of 10 to 13 millions value for some years from 1851, has gradually fallen off since to only about half that amount. Cereal production is already conspicuous in Australasia, at least in the favourable seasons of a climate somewhat uncertain for this industry. In 1879, for instance, the young and still comparatively small colony of South Australia had 400,000 tons of wheat to spare for export. New Zealand has entered upon agriculture and wheat growing upon farms of colossal dimensions, with all the aids of the most advanced machinery. But already it is said that the like advanced farming at Manitoba, on farms of the dimensions of an English county, must extinguish the rising Australian prospects, on account of the greater proximity to this country. I do not, however, expect this result. The effect of a still considerable gold export in reducing homeward freights is in favour of our remoter producers. One of the earliest and most conspicuous effects of the gold discoveries in Australia was a fall to one-half in previous homeward freight rates, because the return cargo for a thousand great ships, with capacious holds full of ordinary merchandise, was only a few cubic feet of gold.

#### *India our Chief Customer.*

Our foremost figure in colonial commerce has of course been India. For the last ten years her average imports of merchandise have been 34 millions, and exports 58 millions. Of the latter about one-half comes to this country. One remarkable feature of Indian trade is the great excess in importation of treasure, chiefly silver, as compared with exportation, the respective totals for those ten years having been 91 millions and 22 millions. Besides the raw cotton already alluded to, her great opium export is only too notorious. That, however, is directed to China. It amounts in value to no less than one-fifth of the whole yearly merchandise export trade. The article jute, so useful for all rough sacking, has advanced, from less than a million sterling twenty years ago, to upwards of three millions now. Indigo is now exported to the same annual amount. There are considerable amounts of rape and linseed, rice and sugar, and already the new export article tea is up to three millions of yearly value. India, in short, with her vast population, her sixty millions of revenue, and already nearly one hundred millions of merchandise trade, gives the largest figures of our outside empire. Largely exceeding the parent in population, she makes no distant approach in amount of revenue. But India, as before remarked, is not in the proper sense a colony. The comparative vigour of progress in the true colony is well illustrated in the striking fact that already the united Australasian group has a total of trade almost equal to that of India.

### III.—COMMERCIAL PRINCIPLES AND PRACTICE, AND TARIFF RELATIONS, AS BETWEEN THE MOTHER COUNTRY AND COLONIES.

#### *Retrospective Glance.*

We shall not readily or fully understand the very interesting and important but somewhat complex problem of the present tariff relations of

our vast and diversified empire, unless we take a considerable retrospective glance. Our colonial empire of a century past, such little as there was of it then, has altered and advanced politically as strikingly as in any of its other features. Prior to the American disruption, a British minister could declare in Parliament that a colony had no right to manufacture for itself even a nail to a horse shoe. Protection to and protection from was the reciprocal rule, until we at home expanded our views into that free trade which has been our rule of commercial government for the last thirty-five years.

#### *The Differential Duties Act of 1850.*

What still regulates fundamentally the colonial tariff system is the Imperial law of 13 and 14 Vict., commonly known as "The Differential Duties Act," but which in fact is only the section of an Imperial Act of that date for the better government of the Australian colonies. In introducing this most important measure, Lord John Russell explained that, having the previous year put an end to monopoly by repealing the Navigation laws, this would put colonial as well as home tariffs on the broad free basis. The main object of the Act was to check reciprocity or protective arrangements by prohibiting differential duties. Each colony was to admit at the same duty the same kind of import from whencesoever arriving.

Colonial discussions and contention over the tariff restrictions of this Act have been ceaseless ever since, and have resulted in some modifications which I will briefly point out. In conceding constitutional self-government to the more advanced and independent colonies, the Home Government has practically allowed to each separate Colonial Government the control of its own tariff. Each colony might thus protect its own producers, but could not, in face of the Act alluded to, engage in protection or reciprocity outside, even to adjacent sister colonies.

#### *Modifications of the Act—as to Canada.*

The first vigorous movement towards a freer colonial tariff came from Canada. The tariff question was indeed a chief consideration in that other movement which in 1867 resulted so successfully in establishing the great union of British North American colonies now known as the Canadian Dominion. The Canadians complained that they were unfairly exposed, along their whole frontier line, to the closely protective system of the United States, which could flood Canada with goods by aid of our own Differential Duties Act, and yet refuse all Canadian goods in exchange. But now, by union under the one Dominion Government, the various associated colonies can interact with the freedom permitted previously to a separate colony.

#### *As to Australia.*

On this fertile tariff question, the Australian colonies were promptly in the wake of the Canadian. They claimed a good deal more, and argued stoutly for complete intercolonial liberty, and in some cases for even that of direct tariff arrangements with foreign States. The Home Government, while rejecting these views, the ten-

dency of which, as was properly remarked, to break up the empire, is favourable, would not be opposed to Customs unions more complete political union, between colonies, so as to give the intercolonial freedom conferred upon Canada. The Australian colonies had already strongly felt the cost or necessity of some such union, as, for instance, in the border-duty difficulties along the Murray between New South Wales and Victoria.

#### *Amended Tariff Act, 1873.*

In fine, there were two elaborate and spatches on the whole question from the Colonial Secretary, Lord Kimberley, respectively 13th July, 1871, and 19th April, 1873, and these, after due response from the colonies, resulted in the amended Imperial Tariff Act, May, 1873, which seems to have closed the question for the present upon the intercolonial tariff. Although this is only an Act "with respect to Custom duties in the colonies," yet, with the usual understanding of such cases, it is applicable to all like colonies. By this Act, these Australian colonies, or any two of them, are free to make reciprocity arrangements as they please: 1st, that, as regards other countries themselves the Differential Duties Act of 1850 applies; and, 2nd, that there be no derogation of existing imperial treaties. From it may be inferred that, certainly, the colonies of any colonial group, and separate colonies whatever, may make arrangements to the exclusion of the mother country as well as all other places, or colonies outside of themselves. Indeed, the Act of 1873, still standing as it does upon the same basis, requires this most odd-looking prospect, seemingly as it must appear towards the mother country as well as others of the family.

#### *Importance of the Tariff Question.*

The whole tariff question is most in the empire's future. It is sure to be raised with reference to the diversified conflicting tariff views of our colonies. It is at this very time sitting in London, the Tariff Congress, summoned by the Canadian Tariff Commission, and representative of the interests of the whole empire, the avowed aim is the promotion of some reciprocity for the empire. In one of his despatches, Lord Kimberley remarks that if all the colonies but follow the free-trade principles now acted upon, and with such decided advantage to this country, all tariff difficulties would disappear. But, unfortunately, all the colonies do not follow the free-trade principle. Most of them, indeed, have their lot with their mother's free-trade in the younger cases, such as that of the colonies, have chiefly continued the tariff system implanted by imperial influence at the commencement; but others, and more especially the great Canadian Dominion, and Victoria, have relapsed into protection or into a variety of reasons or excuses.

On the subject of this colonial tariff question we have a recent Parliamentary Report (Foreign and Colonial Import and

o. 120 of 1880), showing the rates of our principal colonies upon leading hortation. These have, in no small tances, a protective character, more he case of the Canadian Dominion; he same time, as the report justly aties of this character are in general e as compared with those of some ies, of which a table is also given f comparison in the report. Thus ates upon certain manufactures are to 30 per cent. in the Canadas and ers of the colonies, in the United er foreign countries, they are 50 per en 100 per cent. *ad valorem* and

ction means economic or material red with the free direction of labour, es readily admitted. But it is con- colonial protectionists that social or derations are of prior consideration economic. Unquestionably they are. time, as our country from the free- int would urge, if the economic be a real fact, there ought not to be interference with free commercial for very clearly demonstrable social ecessity. We may, I think, fairly ur country's experience has been to all the general interests of a people r best chance under the fullest free- s.

#### THE CONCLUDING REFLECTIONS.

##### *Resemblances of other Empires to ours.*

three great and somewhat similar world, namely, that of Russia, that States of America, and that of our There are of course other countries, ming to be empires. But these three pecial resemblance alike in their acts, and in the problems they have in the government of remote and separate societies. With certain in all three, there is one most erence between our empire and the e the latter have retained effective ol to the furthest extremities respec- great areas, our Imperial Govern- tionally, to a very large extent, given ol, in successive concession to the he vigorously progressive self-sup- self-governing societies which we sfully planted in almost every great world. This question has a direct th the subject of my paper; for differences, and the eagerness with any seems instinctively to contend rriff license, are together, perhaps, et cause of this segregative action. e, in its aspects alike political and forms that "colonial question" w of our future hold upon the dity spread over our grand domain, ally rising upon us here at home ; dozen of years, but which I must ter upon in the restricted limits of

##### *The Colonial Question that "Trade follows the Flag."*

But keeping strictly to the commercial part of the question, there is one section of it on which I may still offer a few remarks. We are all familiar with the phrase that "Trade follows the Flag;" and perhaps we are equally familiar with the counter assertion of what is called "the Manchester school," that trade has no such partiality or nationality, and follows no flag in particular, except that of its own interests. The difference of view here is due to what makes differences in so many cases, namely, the pursuit of an abstract or deductive reasoning, without regarding the frictional surroundings of the facts of real life. The expatriated colonist, who turns his eyes back to his old home, and methodically, and as of course, sends his goods to that market, and orders his requirements out of it, is perfectly convinced that as a matter of fact, all theories notwithstanding, trade does follow the flag.

The reconciling explanation is really much simpler than most people who enter upon the question are accustomed to imagine. There is nothing more in the flag doctrine than simply the differences or difficulties of a foreign as compared with one's own nationality. There are three main obstacles in the path of foreign commerce, from which our own commerce—home or colonial—is free. First, there is the foreign element in its comparatively repellent effect; second, the different speech; and third, the different moneys and weights and measures. The whole constitute a natural "protection," tending, even for successive generations, to bring the bulk of a colony's commerce into the parental market rather than any other.

A very simple and direct illustration of the flag doctrine is supplied by the school boy who, penny in hand, is confronted for his custom by two competing applewomen. If these old ladies were exactly a match in themselves and their appurtenances, the smallest possible difference—the direction of the wind, or the matter of a half inch of distance—might suffice to determine his preference. But suppose one of the women to be a foreigner. Suppose, again, that she was unable to speak the boy's own language. Even if he had no further botheration about her foreign weights and money, he might be persuaded into accepting even the smaller apple of the two from his own country-woman.

No doubt the "flag" effect has its limits. It may stand good at 1 per cent., and be overborne at 2 per cent. of difference. But in these days of industrial efficiency and close competition, some such small difference as the 1 per cent. may involve the whole, or nearly the whole, case. We see this remarkably exemplified, year after year, in the fact that almost every bale of our vast colonial wool clip is sent to and sold in this country, although often one-half, or even considerably more, of what is dealt with at the great London wool sales, is immediately re-exported to other countries. I cannot, therefore, agree with those, and they are still a large, although, as I am happy to think, a diminishing number, who hold that is of little consequence, commercially considered, whether or not our colonies

remain part of us. Mr. Goldwin Smith, amongst others, has told us that "Free trade wants no colonies. It can be carried on as well, if not better, with nations that are independent, as with those which have a political connection with Great Britain." All this, I reply, is only a further instance of that abstract reasoning already alluded to which overlooks experience and the facts of life.

*The Imports and Exports Question—Problem of excess Imports.*

Let me turn to quite another subject. Much importance has been attached to the remarkable preponderance, especially in late years, of our home import over our home export commerce. If we examine our colonial returns, and those of new offshoots generally, there is commonly excess the other way, at least after that first stage of their life during which such countries or colonies are supplied largely from outside, until they have organised their own labour. It is important to bear in mind this fact as regards our colonies, because it helps to explain the quite opposite feature of our home commerce.

I return to Mr. Bourne, who has given an unusually full and accurate explanation of a feature simple enough when thus explained, but which has puzzled and even alarmed many who had less mastery of the subject. Taking, for instance, the 20 years from 1857, the average yearly excess of net imports over net exports (that is, of imports retained for consumption, and of exports of our own produce) was about 60 millions. Mr. Bourne then explains that about one-half of this apparent excess is due to mere omissions in the method of our official reckoning, as, for example, when we omit from exports the ships and steamers we are constantly supplying to outside buyers, all of which vessels, with their stores, more especially of coal, are as real exports as anything else, and make up collectively a large yearly item. Again, there must be excess imports from wear and tear, and increasing use in the arts. And yet again, from the recorded import values we must deduct the cost of bringing the imports, a cost which of itself a careful estimate has made as much as 11 per cent.

Thus the 60 millions excess imports are reduced to about 30. But these 30 millions also entirely disappear when Mr. Bourne finds, on a balance of estimates, quite that amount to be due to us yearly as interest or dividends on colonial or foreign loans, or other outside investments. If this has not been quite 30 millions for the whole twenty years in question, there remains yet a very great deal more to be counted in the same direction. First, there are the drawings on India, which latterly average 15 millions yearly. Second, the profits of the import and export trading, as well as the freight earnings of our shipping. Third, and lastly, the earnings of our people abroad, remitted to be spent or invested here. All these credits to us must be paid in imports, and, as Mr. Bourne in effect remarks, so completely do they turn the scale, as to leave to be accounted for, not a great excess of imports, but, on the contrary, no inconsiderable excess of exports, which, as he properly adds, must still swell the outside indebtedness to this country.

The further and complete explanation appears to me, is found in a direction quite overlooked. It is due to the fact that our export account by the payment loans or other advances we are so constantly making to colonies, countries, or other parties. Mr. Bourne, in short, has shown that problem is not an unaccountable excess of imports, but rather an unaccountable excess of exports. The export excess, as I would call it, its solution in a due allowance for our loans or other advances, all of which are eventually to be paid or balanced by exports.

Thus we can better understand the great excess of our trading returns during our payments in the earlier part of this century. Mr. Bourne, by an estimated correction of the real values, finds that in the year 1816, for our net imports were only 17 millions; no less, comparatively speaking, than 41 of net exports. This export excess, he says, appears to have gradually abated since 1825, when the modern feature of this excess of imports began.

These considerations help us to deal with remarkable figures of excess imports in trade returns for the last few years. For the years, 1871-80, the average yearly import has risen from Mr. Bourne's rather early estimate of 60 millions to 99 millions; and for half of that term, namely, the five years, the average yearly import excess is no less than 137 millions. There is also the additional fact so unfavourable by rule or rote to a certain alarmists, of a decided falling off in export with decided increase of imports. As in this way are in fact quite exceptional, allow me to present them more fully. Our exports appear to have culminated when they reached a total of 315 millions that year the total imports were 35 millions. For the eight succeeding years the exports declined, until for 1880 they are only 22 millions; while on the other hand the imports kept increasing, until in 1880 they reach the very total of 410 millions. How is this problem dealt with?

*Explanatory Considerations.*

I utterly reject the dolorous explanation indulged in, that, in such increased import and reduced exports, we are devouring our own income, and are besides being driven more and more expelled from markets by too successful foreign rivals. The facts of our business life, present as we are entirely opposed to both these conclusions. Certainly there has been no such change in our spending habits during these last eight years as to make us now utterly disregard the value of our earnings. On the contrary, our still calculate, on sound data, the many millions of the annual savings of the country; and our tax returns are standing proofs in confirmation. No doubt our distinguished Premier's Budget speech last month, lamenting the income-tax, which had rolled up with huge steps from £750,000 a quarter of a century ago, to £1,990,000 for each penny for the years 1877-8, should, three y

be estimated at only £1,943,000. Well, so But the smaller amount is hardly one whit less effective than the larger in overturning our old views. By way of accounting for this check and reaction, most of us may still recollect some exposures of hollow trading towards the end of 1878, the most prominent instance of which was the notorious City of Glasgow

But we are left to explain, in some other and better way, the features in question. I have previously alluded to a comparatively unnoticed feature—the increase due to our exports from our colonies, from time to time, great outside payments. I have now to notice a feature just the reverse, and almost equally overlooked, namely, the effect upon our imports of any great repayments of such principal sums. We have been receiving largely such repayments of late, in part from the United States; while further, tending to the same effect, namely, that of increasing our imports and reducing our exports, France and the States are beginning to compete with us in supplying the poorer outside world with capital.

The United States, as is well known, have been making most strenuous and exemplary efforts to reduce or extinguish the great public debt bequeathed to them by their civil war, and this has been especially the case during the last three years. Great part, probably the greater part, of these repayments, have come to this country. As bearing me out in the general conclusion which I have been presenting, let me give you import and export figures of the States. For the imports are 98 millions as against 122 millions; for 1878 they are respectively 86 millions, and no less than 145 millions; for 1879, 103 millions and 151 millions; and for 1880, respectively, 139 and 178 millions. These are startling figures, equally so, indeed, with those in the exactly opposite direction; but both are equally explicable on the principles I have endeavoured to lay down. They are not merely the indication respectively of either great profit to the one country or great loss to the other.

If we have received of late unusually great sums, thereby swelling our import figures; if we have used these largely to improve our colonies, instead of sending them again abroad, thereby tending to comparatively reduce our exports, we may not, by such occasional variety in our economic procedure, be promoting less than at times the general well-being.

*As to Mother Country and Colonies, and its Feature of Accelerating Progress.*

I need now but a few words, in conclusion, upon the future of our progress, or more properly of our accelerating progress, which I have already briefly referred to. Dr. Benjamin Franklin, in his list of instances of long suspended life in the colonies, expressed the wish that his own life could be suspended for a hundred years, in order that he might see the expected great progress of the colonies. That hundred years has just passed; the patriot philosopher could now return to the advance of his great country, it would by far surpass even his most sanguine anticipations.

Again, it stands recorded of our postal service, and the record is so little removed from us as to be found within the preceding century, that the mail from Edinburgh to London conveyed, on one occasion, but one letter. What would a Franklin *redivivus* of those small postal times say now, or how could he possibly have anticipated the aspects and dimensions of a modern mail between the two capitals!

If we are to judge by the past, and more especially the recent past, the waking up to a further century of progress would present a vast advance, as well as a marvellous change of aspect, as compared with even the present great attainments of our empire. If the empire is still, as we all hope and wish, to hold together, and this, with due care and precaution, where all parties are so agreed, ought not to be impossible, we may expect that even the short space of a century might produce incalculable changes. Prior to the present age, a century did not very much alter any part of the world, even if our comparison include the best and most progressive days of ancient Rome and Greece. But in a further hundred years, at the apparently geometric acceleration of pace upon which we have entered, what may be the aspects and progress, for example, of the great Canadian Dominion, of the almost boundless expanse open to the Cape Settlements, and, more perhaps than all others, what the advance and change of the Australian colonies?

The mother country's progress may continue the marvel we have just alluded to in her postal business; but she will certainly be far surpassed by the relatively quicker progress of most of her colonial children. In the *Statistical Journal* of last year (1880, pp. 491-4), Mr. Price Williams has given us some curious results of the estimated future population of this country. Going much beyond a mere hundred years, he finds limiting causes which will prevent Great Britain, for instance, with its present 29 millions, having more, as far on as A.D. 2231, than 132 millions; or upon another and more hopeful calculation, 176 millions for the year 2181, or three centuries hence; while London in the same time is to rise from 3,700,000 to only a little over nine millions. My own idea would be to extend very greatly this calculation, even for our parent State; for in these days of enterprise and progress people will be born into the world, and once there they will contrive to keep themselves alive and comfortable by aid of all the science and the business facilities and resource of their day, and they will again quit the world only to leave families of still greater numbers behind them. But in any case our colonies' progress is not restrained by any of the narrower circumstances that may be supposed to tell against their common parent. Those of us to-day who, as Franklin did last century, enjoy a mental excursion into the future, have there a free domain before them, and an assurance that they can hardly be too sanguine in their expectations and estimates. Let us hope that our great grandchildren, who are actually to realise all our present guesses, will still look upon a united British Empire, which is destined rather to be held more firmly together, than to be disunited into fragments, by the accumulating weight of its great future attainments.

## DISCUSSION.

Mr. Stephen Bourne said this subject was one of immense importance, and he believed it would grow until it forced itself on the attention of economists and statesmen to an extent at present not dreamed of. The progress of other nations, as well as our own, was a point which required to be borne in mind, for there was no doubt that both France and the United States were increasing in the amount of their trade more rapidly than we were. This was not a thing to be mourned over, for if we believed that trade was good for as it was good for the rest of the world, and we could not be surprised at younger nations overtaking us, and by their own progress adding to the general welfare. At the same time it was very important that we should not go backward or neglect opportunities for further progress. He quite endorsed what was said in the paper as to the contrast between official and real values, and was glad to think that the allusion to the subject would lead statisticians and economists to see the danger of contrasting the figures of the present day with those of many years back, without understanding the difference between them. If one took the price of bread or meat in the time of Queen Elizabeth, and compared it with present prices, it would show how fallacious a comparison founded on money value must be, if uncorrected by the quantity of the article referred to. If this were not attended to, statistics, as had been said, might be made to prove anything, whereas, if treated honestly, and with due information, they were most valuable. He thought Mr. Westgarth had rather underestimated the amount of our colonial trade as compared with our foreign trade. The fact was our colonial trade, both export and import, had been growing more rapidly than our foreign trade. This was a satisfactory feature, because it was of very great importance to keep up our trade with those allied to us, and it showed the advantage of our efforts in aid of colonisation. It was quite certain that trade to a great extent followed the flag, but he did not attribute this altogether to attachment to the flag. No doubt that had an influence, but in addition to that a colonist had greater credit in his native country than elsewhere, and colonial trade grew up principally on credit. But whatever the truth might be, the fact formed a very good reason for endeavouring to promote emigration to our own colonies rather than to the United States. A friend of his in those States recently suggested to him that it would be a good speculation to invest in some of the land companies there, and no doubt money was to be made in that way, but whatever his ideas of the wisdom of such an investment might be, he could not consistently assist emigration to the United States in preference to our own colonies, whilst the former acted in such a hostile manner towards us in respect to the tariff. Canada was now doing something of the same kind, but he hoped she would soon see the wisdom of making a change. He could not recommend anyone to emigrate to a colony which did not establish perfect free trade between herself and us. He had some later figures than those quoted by Mr. Westgarth, showing that in 1880, out of a total trade in cottons, woollens, and iron goods, to the amount of 223 millions, 124 millions were with the colonies. That being so, one could readily understand how any depression in those three great branches of trade was felt so extensively throughout the whole country. It was impossible to over-rate the importance of the tariff question, and his decided opinion was that the true solution was only to be found in the mother country and all her colonies having one uniform tariff, both for customs and excise duties. The man who took his drink of brandy in Norfolk paid the same amount to the revenue as the one who drank brandy in Middlesex, and he held that the man in Canada, or Australia, should do the same. If the colonies required to raise a larger revenue, they should do so in some other way. That

would be a better system than to endeavour to make the mother country to allow the imposition of protective duties against herself as well as the world besides. However much clamour might be raised in support of such a scheme, he believed Englishmen would ever retrace the matter of free trade, and he was sure that if they did, such action would be a death-blow to English commerce. With regard to the vexed question of imports and exports, Mr. Westgarth had correctly stated the gist of the question, but he had himself laid it down some years ago, and read before the Statistical Society. There was no doubt that the average excess of imports over exports was reducible to about 5 per cent, and it was fully accounted for by the receipts had from our investments abroad, and the earnings by our ships in carrying the goods, the object of the paper from which these points had been extracted, was to show that although the state of things in times past, it was entirely altered. In the earlier history of our country we exported largely in excess of our imports, though no doubt the maxim of Adam Smith, that whatever a country imported must be paid for by exports, was true, it was true only over a long period of years, it did not follow that it was true in any one year, or that circumstances might not be such as to alter the object in that paper was to point out that we had a preponderance of exports we were not making because we were making loans to the foreign countries. For instance, when the United States was developing her railway system, we supplied her largely with railway iron, but we took American bonds and securities; and hence, although we were exporting largely without any apparent return, we were making America our debtor, and held a lien on her property. At that time we were growing the food we needed, but now we grow much less than we required; America was supplying us with the food we were paying her, unfortunately, not with the food we needed, but by writing off her obligations to us, no doubt whatever, that for a series of years we had been rating up her capital to the value of millions a year, and America had been paying us by the food she had been sending us in the form of gold which some people would not set in until America had sold all her bonds and other securities held in this country, but when that was done, if the present state of things continued, the result depended on the wisdom with which we managed our affairs. If a man with a large family, who found it difficult to earn his bread and butter for them all, allowed them to be idle, or spending their time in painting or adorning the garden, instead of earning, should tell him he was doing wrong—wasting his capital—and that the only result could be that he would be ruined. And it was just the same with a country. If we were spending more than we were earning, it was just the same. The large excess of imports had entirely in articles of food, and if that food was sent into human mouths, to be employed in making goods for export to pay for it, he did not see how the food was imported; but if, on the other hand, the food supported, either could not find employment, or was devoted to unproductive purposes, living too fast. What we wanted was to increase our trade, and if foreign countries were sending us goods, we had a grand resource in our colonies. An economical consideration showed that we ought to every means to stimulate emigration to our colonies, thereby saving the lives which we were

ing and unsanitary arrangements, and at the raising up customers, and enlarging our own

rewater said Mr. Bourne's conclusion seemed unlimited free trade would be a very good if we had a condition of things which was to occur. He congratulated Mr. Westgarth, which some years ago would, no doubt, exceedingly satisfactory, but, at the present were many things which tended to show trade was not such a universal panacea as it presented. It appeared from the paper that as improving in her commercial prosperity, with England's decline, and the question of America was right or England. It was a thing that the two greatest Republics in together refused to adopt the teaching of the latter School, and went in for protection. Both flourishing, but in England, Consols par, land was greatly reduced in value, and re all complaining that they had lost their tactically, the money was being drained out of the country. Working men had cheap food, but they were beginning to see that they could not have the loaf at 1s. with money to buy it if they had no money. The question was means so clear as it was represented, and it was doubtful whether an exactly opposite system could be adopted.

Mr. Man said he hoped succeeding speakers to further into the subject of free trade, but the subject of the paper.

Mr. Ham Botly said he would attend to the request, although he had never heard fallacious or opposed to common sense than advanced by the last speaker. The paper was a valuable one, and it was very important to show what good customers for our manufacturers our colonies. Only a day or two since, he went from Melbourne to the effect that the exports from Melbourne, Adelaide, and Sidney, in the month to Great Britain had been:—Wool, 1,800 bales; tallow, 4,800 casks; copper, 900 tons; wheat, 53,000 qrs.; flour, 75,000 barrels; 22,000 ingots. He had as much correspondence from the colonies as most people, and the letters received within the last few days, fully corroborated the views of Mr. Bourne. In Canada there was a demand for agriculturists, if these had skill, capital, and energy, but helpless waifs and strays who would not be on any country were not wanted. It was impossible for England to do without free trade, though he was a small landowner himself, and that if landowners demanded protection against the increasing of their rents, they ought to be met on the sea.

Mr. Scoble said it had been clearly shown that colonies which had not followed England's free trade policy, had made more rapid progress. At the present time, England had the whole world against her, and the question was where she was to obtain a trade, by which to pay the interest which she required. It appeared to him that she ought to legislate as to induce our children to come from the home country to the colonies, and that, under the British flag, might be made to require, and that we in return for our commerce increase. He could not see that Mr. Bourne, that a uniform tariff for all our colonies ought to be in place, there might very well be differential duties for different colonies which required to raise more revenue for their own purposes. Everyone would agree that the colonies should be fostered and protected as far as possible.

Mr. Clements said he had never listened to a paper which had given him more satisfaction than the present. He thought all countries should have perfect liberty to adopt any fiscal system they pleased. This country had obtained considerable advantages by free trade, but these had not been unqualified advantages, and concurrently with its introduction had come the development of the railway system, and other matters which were great factors in the increase of English commerce. The excess of imports was, no doubt, due to the increase of population, being principally in articles of food, the English farmer not being able to compete with the American in the growth of corn. He thought English farmers should turn their attention to other kinds of produce, such as milk and vegetables, which would pay them better.

Mr. Cook said he would not now speak of free trade, but he thought that at some other time it might very usefully be discussed. He should like to know, when it was said that the excess of imports consisted of payments for investments in foreign countries, whether it was merely the interest we were receiving, or the capital; if the latter, what was done with it? If we were paying for our food with it, we were certainly living on our capital.

Mr. Trelawney Saunders could not miss the opportunity of impressing on the public the importance of the colonies to this country, and of this country to the colonies. With regard to the doctrine of the flag, he could not imagine a stronger instance than the trade we did with the United States—people of our own race and language; in consequence of this question of the flag, we exported less there than to Australia, although the population was twenty times as large. The colonies were necessary to this country if we were to rely on our own soil for our food. Without enlarging upon the vexed question of free trade, he would venture to remind the gentlemen who spoke so despairingly of the present condition of things, that within his own memory there was not a farmhouse where the men did not eat barley bread; now such a thing was unknown, and the conditions of society had improved in like manner throughout. A remark had been made that they must be careful in all their discussions to avoid politics, and he quite agreed that they should not go into party politics; but until a question became one of party it ought to be open to them, and it was impossible to consider colonial questions without looking at their political aspects. The question of tariffs could only be settled on the basis of common legislation at present, because the colonies were not represented. Until that was done, it was no use talking about intercolonial or international tariffs. He hoped some opportunity would be given, either in that Society or elsewhere, to consider the manner in which a union of the colonies and the mother country could be brought about. It was a question which could not be allowed to slide, for every day personal interests were growing up which constituted obstacles in the way of union. The only centre from which union could be brought about was the mother country, because Australia and Canada would not of themselves see any necessity or advantage in being united with each other. The colonies owed their existence and protection to us, and he thought they would be willing to take their fair share of the burden and responsibility. He felt sure that a severance of the colonies from the mother country would have the same effect as the breaking up of the old Greek republics; we should simply become the prey of the common enemy.

The Chairman said they would all agree in the importance of the colonies to the mother country. It was the rule here not to go into political questions; but, as had been said, it was quite impossible to deal with such a question as the colonies altogether apart from it. He begged to propose a cordial vote of thanks to Mr. Westgarth for his extremely interesting and valuable paper.

The vote of thanks having been carried unanimously,

Mr. Westgarth, in reply, said time would not admit of going at length into the many questions that had been raised; but he thought Mr. Bridgewater, like Mr. Ruskin, regretted these times of hurry and progress, and would like to go back to the old sylvan days, when everybody sat quietly under his own fig-tree. He would only say to him, that one of the favourite arguments of Protectionists was, that in England wages were so high, that the manufacturer in this country required protection against lower wages elsewhere.

#### TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 11th, 1881; Lieut.-Colonel DONNELLY, R.E., in the chair.

The following candidates were proposed for election as members of the Society:—

Betts, Edward Peto, M.A., The Holmwood, Bickley, Kent.  
Clark, Robert Ingham, West Ham Abbey, Stratford, E.  
Cottrell, James Maskall, 340, Brixton-road, S.W.  
Glover, William, Tower Chemical Works, Victoria Docks, E.  
Grant-Duff, Malcolm, Imperial-chambers, Bowalley-lane, Hull.  
Trelor, William Purdie, 69, Ludgate-hill, E.C.

The following candidates were balloted for, and duly elected members of the Society:—

Allison, Herbert John, 41, Southampton-buildings, Holborn, W.C.  
Baggallay, Henry Charles, 4, Ada's-avenue, Hull, Yorkshire.  
Blakesley, John Holmes, M.A., 23, Popstone-road, South Kensington, S.W.  
Elliott, William St. George, M.D., 39, Upper Brook-street, W.  
Favarger, Henri, 75, Turnmill-street, E.C.  
Heseltine, Francis J., Westminster Palace Hotel, Victoria-street, S.W.  
Inglefield, Admiral Sir Edward, K.C.B., 99, Queen's-gate, South Kensington, S.W.  
Keefe, John, Colquitt-chambers, 6, Colquitt-street, Liverpool.  
Longworth, William, Guildford, Surrey.  
Matthay, George, F.R.S., Cheyne-house, Chelsea Embankment, S.W.  
Ramsden, John Carter, Gristhorpe-hall, near Filey, Yorkshire.  
Ravenworth, Earl of, 9, Mansfield-street, W.  
Severn, Walter, 9, Earl's-court-square, S.W.  
Snape, William, J.P. (Mayor of Over Darwen), Lynwood, Darwen, Lancashire.  
Sproston, Hugh, Hughville, South Norwood, S.E., and Demerara.  
Thornton, Edward, C.B. Bank-house, Windsor.  
Warren, W. J., Cotford-villa, Bournemouth.

The paper read was—

#### THE MANUFACTURE OF GLASS FOR DECORATIVE PURPOSES.

By H. J. Powell, B.A.

"The manufacture of glass for decorative purposes" is a subject of considerable extent, and requires more time to do justice to it than is at present available. The subject may conveniently

be divided into three parts:—1. The glass for decorative purposes of the natural glass; 2. The production of decorative decorative material, by the manipulation in a plastic or viscous condition; 3. The treatment of the surface of glass with a view to the effects due to its form or its nature.

#### I.—NATURE OF GLASS.

Glass is defined as an amorphous solid, and the existence of devitrified glass is both crystalline and opaque, and of glasses to which I hope to allude materially damage this definition. The different glasses, but all agree in being compounds which are called silicates being formed by the union of the oxide or silica, with another oxide. The silicates may be divided into two groups being composed of alkaline, and the metallic silicates. It is only necessary a few individuals belonging to each of them, namely, those of the first group, which contain the oxide of potassium, the oxide of sodium, and those of the second group contain the oxide of lead, the oxide of barium. Every silicate belongs to at least one silicate belonging to the group of alkaline silicates, as well as belonging to the group of metallic silicates. Manufacturers have practically no other silicates as silicates, but knowing that the nature of a glass depends upon the nature of the constituent silicates, they put into the materials of such a nature, and in such a way as will produce the silicates, and compounds which they require. The raw materials, as a rule, oxides or carbonates; a carbonate compound of an oxide with the oxide or carbonic acid. The most important are sand (an impure form of oxide of lead (a mixture of the oxides of lead, carbonates of potassium, sodium, barium, and calcium. The whiteness of the resultant glass, upon the purity of the raw materials, and upon the absence of iron, whether as a metal. The silicate of lead is found in direct combination in the crucible influence of intense heat, of sand with lead. The silicates of potassium, sodium, and calcium, are also formed in the crucible indirect action of the sand upon the carbonates. This indirect action consists in the expulsion of carbonic acid gas from the carbonate by the intensely heated oxide of silicon, consequent union of the latter with oxide. Given the alkaline and metallic materials required to form a certain glass, the materials for the required silicates are simultaneously thrown into the crucible, and will be simultaneously produced by the heat of the furnace in which the previously been "set."

The simplest form of a glass furnace base, covered by a flattened dome. The base is a comparatively small round the grate, under arches formed of the dome, the crucibles are placed through the dome at the side of each direct upon the crucibles the heat is

the centre of the dome. The arches introduce and removal of crucibles the removal of glass from the cruci-

FIG. 1.—FURNACE.\*

quired for manipulation. Crucibles are rolled by hand, and their shapes according to the nature of the mixture they are intended to hold. If the

mixture for a glass contains oxide of lead, it must be protected from the reducing action of flame, and the crucible must be closed on all sides, except where no flame can reach. Mixtures containing no oxide of lead are exposed in large open fire-clay bowls to the full action of the flame and heat of the furnace.

Different glasses possess different qualities, according to the number and nature of their constituent silicates. As a general rule, a glass containing two silicates is less fusible, but considerably purer in colour and texture, than one containing a larger number. A homogeneous glass is more easily obtained when its constituent silicates are of similar or approximate specific gravity. Plate and sheet glass, composed of the silicates of sodium and calcium, are generally homogeneous, but possess a green tinge, due to the silicate of sodium. Crown glass is white, owing to the replacement of the sodic silicate by silicate of potassium. Flint glass, consisting of the silicate of lead and silicate of potassium is both white and brilliant. The brilliancy of flint glass is due to the density of the lead silicate, but this very density is frequently the cause of striae and irregularities in the substance of the glass. It is almost as difficult to obtain a clear mixture with the silicates of lead and potassium, as with water and oil. The silicate of barium is used for pressed glass, as a cheap substitute for the silicate of lead. Venetian glass contains three silicates—namely, those of sodium, calcium, and potassium, it is therefore fusible, and its density is trifling. To these two properties the lightness and intricacy of Venetian work are to be attributed. Venetian glass is generally devoid of brilliancy, and very far from being either white or homogeneous, but these very deficiencies give that hazy effect which is looked upon as a characteristic beauty.

FIG. 2.—CRUCIBLES.

glass, in addition to the silicates of sodium, and calcium, contains traces of magnesium and aluminium. It is then manipulated, and developed, with the addition of copper, a ruby colour, which can be obtained with a glass containing silicate of

and purification are complete, the crucible is in a condition closely suited of very glutinous treacle. It can be removed from the crucible by pouring, or by gathering. Gathering consists in holding the heated end of a hollow iron rod,

\* To illustrate this paper have been kindly lent to me by Messrs. J. & F. G. & Co.

measuring from 5 to 6 feet, into the molten mass, and turning it so as to collect a coil of the semi-liquid material. It requires some skill and practice to collect the exact weight of glass required to reproduce a given pattern, especially as a mistake in this, as in all processes of glass manufacture, is irrevocable. The molten glass, as it comes from the crucible, may be considered to be physically porous, as heat produces mutual repulsion between the molecules of a body. These physical pores have to be closed by a very gradual process of cooling, for if the process be hurried, the outer crust will be solidified, whilst the interior remains in a porous condition. So-called toughened glass has failed, because however hard the surface may

be rendered by the violent contraction caused by sudden cooling, the interior remains porous, and the unnatural tension excited between the interior

FIG. 3.—PINK, RUPERT'S DROPS.

and the surface generally ends in the destruction of both. Gradual cooling, or "annealing," is practically effected by placing the glass-ware immediately after manipulation upon movable trays, and slowly removing them in a continuous train from a constant source of heat, or by placing the ware in a heated oven or kiln, and allowing the source of heat to die out.

The effects produced respectively by the refraction, transmission, or reflection of light by glass may, in many cases, be utilised for decorative purposes. If a beam of light be transmitted through a glass prism or lustre, a more or less extended spectrum is formed in proportion to the density of the glass. If white light be transmitted through glass containing the oxide of uranium in solution, rays otherwise unseen become brilliantly conspicuous. If certain metallic oxides be introduced into a crucible, together with the mixture for transparent glass, and be dissolved throughout the mass, the resultant glass acquires the power of sifting the incident rays, and of transmitting effects of colour, according to the nature or quantity of the oxide introduced. Different permanent transmitted colours are obtained (1) by the oxides of different metals, (2) by the different oxides of the same metal, (3) by different quantities of the same oxide, or by different thicknesses of the resultant glass. The characteristic colours of the oxides of gold, silver, copper, manganese, iron, and cobalt are, respectively, pink, yellow, peacock-blue, violet, dull green, and purple-blue. Copper and iron possess two oxides each, namely, a peroxide containing a large proportion of oxygen, and a sub-oxide containing a smaller proportion. The peroxide of copper gives a blue or green colour, and the sub-oxide a ruby red. The peroxide of iron gives a yellow, and the sub-oxide a dull green. Certain oxides are valuable for their power of respectively increasing or diminishing the oxidation of other oxides. Thus, to obtain an iron yellow, which is the characteristic colour of the peroxide of iron, it is necessary to add to the mixture oxide of manganese, which, at a high temperature, parts with its oxygen and its colouring power simul-

aneously. The oxygen thus set free by the assistance of the peroxide of iron has a tendency to part with its and to produce a green colour. The copper has a great tendency to rob of any convenient source, and to produce green, instead of a red; it is therefore when a red is wanted, to mix with it some which absorbs oxygen with greater avidity than the oxide of copper, the reductant carried too far, and instead of having the solution, the metal is found suspended in a state of extremely fine division. In this condition reflects a red colour, transmits an opalescent blue. If the metal be sufficiently large to show its characteristic colour of the actual metal, the known effect of aventurine is obtained. Different colours produced by the same substance are best observed in the case of copper and small quantity of the per-oxide of copper, blue, and a larger quantity a green.

By a strong dose of the oxide of copper, a smaller dose a violet, and a minute quantity the characteristic blue. A layer of cobalt glass transmits red rays, violet rays, and a still thinner layer. Opacity may be produced by the semi-fusion of pulverised white glasses, and by the addition to transparent glasses of some infusible material. Devitri- fication has never been pressed into practical use. The fusion of pulverised glass places at the disposal of the manufacturer a material of great strength, granular and irregular surface, together with the power of developing almost every tint in an absolutely permanent condition. It is also valuable to the manufacturer, as a means of utilising waste. Opaque black enamel is formed by the addition of a parent glass of an excess of an infusible fusible black oxide, as, for instance, iridium, of cobalt, of manganese, or of iron, and coloured enamels owe their opacity to the oxide of arsenic, the oxide of tin, the oxide of calcium, or to cryolite, a compound of aluminium, and fluorine, and their different metallic oxides. It is cryolite which gives the opacity to the well-known hot glass, and is a valuable material. The opacity to the well-known hot glass is obtained by the addition of celain, good specimens of which have been lent by Mr. J. G. Sowerby, of Gateshead.

## II.—MANIPULATION.

The molten glass gathered on the end of a hollow blowing iron may be placed in a mould, and by the pressure of a workman's hand on its inner surface, may be forced to assume the shape of its environment. By this process the glass may not only receive the actual shape of the interior of the mould, but may also be decorated by any depressed or raised ornament, on its inner surface. If instead of being placed in the workman's hand, it be forced into the mould by the descent of a plunger, it will assume on its outer surface the internal shape of the mould, together with any decoration which

pen it, and on its internal surface the surface of the plunger. Venetian glass may also be fashioned by the simple tools of the glass-blower. of the chair in which the workman sits hollow and solid rods by which he rotates the glass with his left hand, the entire mechanism of his lathe. The tools are what may be called the spring tool, the shears, the battle-tening tool, together with a variety of measure sticks, and calipers. However the tools may be, the variety of a blown bulb may be forced to assume any shape. The molten glass, when gathered on the iron, is too fluid for immediate manipulation, and requires to be partly solidified by rolling

FIG. 4.—SHEET GLASS.

polished iron slab, or by insertion in wooden cup-shaped moulds, from which it may assume a rough outline of its ultimate form. The first process in every case is blowing the hollow gathering iron until the glass is expanded into a bulb. If the iron is held vertically, with the bulb downwards, the glass is gathered by gravitation, and expanded at the mouth; if the bulb be raised and blowing continued, it increases in circumference only. The glass may also be elongated by gravitation and by a swinging motion. Whilst the glass is shaped with the spring tool, it must be kept in constant rotation by rolling the iron on which it is attached upon the arms of the lathe, as otherwise it would collapse. If the bulb, remote from the blowing iron, be opened, and the bulb be rapidly heated simultaneously, it will suddenly burst by centrifugal force into a flattened disc. The disc may be re-heated, and the iron held perpendicular to the disc downwards, the disc will rumple and collapse. The heat required

to renew the plasticity of glass essential to manipulation is obtained by inserting the bulb or vessel into the mouth of a heated crucible, or into a furnace adapted to the purpose. If to the end of a solid mass or hollow bulb of glass a second working rod be attached by a seal of glass, and the workman recedes whilst retaining the blowing iron, and an assistant recedes carrying the second rod, the bulb or mass which unites them may be indefinitely extended. If a connection be formed be-

FIG. 5.—LONG VASE.

tween a source of molten glass, and the circumference of a heated wheel, and the wheel be caused to revolve with speed, a thread is coiled upon the wheel in an extreme state of tenuity. This thread may be spun into a decorative fabric.

### III.—TREATMENT OF SURFACE IN ORDER TO SUPPLEMENT EFFECT DUE TO NATURE OR FORM.

*Decorative surface obtained by blowing into moulds.*

Venetian sheet glass.

Ribbed and diamond moulded table glass.

*Decorative applications to surface by heat.*

1. Coloured and metallic gems, seals, and frills.
2. Etchings in gold leaf.
3. Sections of variegated cane.
4. Threading, imitation leaves and feathers, and various forms of threading.
5. Reticulated enamel ornament, with bubbles.
6. Metallic, coloured, and scale decoration.
7. Frosted glass.
8. Iridesence.

*Decorative applications without heat.*

1. Iridescence by corrosion and decay.
2. Cutting.
3. Engraving.
4. Sand-blast process.
5. Acid.
6. Carving. Specimens lent by Mr. Thomas Webb, of Stourbridge Glass Works, Stourbridge. The origination of the process is due to Mr. Northwood.
7. Enamel painting and gilding, fixed by heat.
8. Mosaic transparent glass.
9. Mosaic opaque glass.
10. Stencilled opaque glass.

Such are a few of the processes now in the manufacture of glass for decorative purposes. Additional and improved processes will be introduced as long as the demand for glass continues. The style of the products of flint glass manufactories has so completely changed in the course of a few years, that it is difficult to foresee upon what lines the manufacture of the future is likely to run. The change is indicated by the fact that whereas flint glass was almost entirely sold by weight, sale by the piece at the present time is an exception. T

FIG. 6.—WINE-GLASS.

indicates a loss of a staple product, namely, the heavy ware of medium or common quality. The majority of this ware is now produced on the Continent; the remainder has been retained in England by the perfection of the material of pressed glass, and of the mechanism by which it

is produced with profit, considering the increased competition. English flint glass makers are now mainly turning out the best table glass and decorative glass, and their profit depends upon the invention of novelties. The only safeguard of these branches of manufacture is to adopt a style and an English standard. The standard must be determined by consideration of the vessels produced, and of the nature of the labour upon the decoration of them. It is, for instance, undesirable to prolong labour upon the decoration of vessels which are essentially fragile. The forms and the quality of the wares produced must be elegant, and every care must be taken to develop the natural properties of the material. The standard must be the highest possible, and every vessel should be allowed to leave the workshop which is not perfect both in material and in workmanship.

Effectual assistance in the competition may be derived from the adoption of improved methods of working and the application of proved knowledge and of greater economy in all the processes of manufacture. It will be advantageous if workmen and manufacturers can discover that their work is identical. The Flint Glass Makers' Society has made mistakes; but there is no valid reason for antagonism, and it is due to the increased sobriety, intelligence, and productive capacity of the workmen.

FIG. 7.—APPLICATION OF HANDLES, SCROLLS, &amp;c.

is produced. Pressing glass is a manufacture by itself, and the loss remains to the workmen, and manufacturers of flint glass. Decorative glass has taken the place of that which has been lost, but it is doubtful how long it will be possible to produce

## DISCUSSION.

Chairman, in inviting discussion, said he hoped Webb would give some further information on this same subject.

Webb said he should have been happy to say more, but really there was nothing to add to the full information which Mr. Powell had given.

Chairman said he was not practically acquainted with the manufacture of glass, but had done a little at the museum, and had often witnessed the marvellous skill with which the glass-cutter could tell whether the piece of glass was of uniform size without a scale. Some time ago he endeavoured to get up a society in the City, one of the objects of which was to practice glass-blowing, metal and wood turning, but unfortunately, the scheme fell through. With the colours which had been mentioned. When oxides were treated by various re-agents in a flask, the different colours would be seen, produced by rays of light passing through the substance. It is known that colour was caused by certain rays being absorbed, and others being allowed, or being reflected. If all the rays were reflected, the colour was white; if they were all absorbed, it was black, but if some only were absorbed, a colour would be caused. He understood with competition was very severe in the glass at that was the case with many other trades as the sand-blast was shown in operation at the exhibition at South Kensington some years ago.

Chairman said that as there seemed to be inclined to discuss the subject, he must conclude proceedings by proposing a vote of thanks to the reader of the paper. He must say he was pleased that there was no discussion, for the paper was so full of matter, that they yet been hardly able to sort it in their mind. There was, as Mr. Powell had told him sitting in the room, enough matter in the paper for lectures. As far as he was concerned, one of the ideas brought home to his mind was, that at the present time, machinery had little to do with the rough tools with which the beautiful articles were made, he thought that even Mr. Powell might find some pleasure in contemplating the manufacture. There did not seem to be any action of the subject in which machinery intervened, except in that one process of the cut; and it was certainly some satisfaction that there was still one branch left in which real skill had to do the largest portion of the work and they could all reciprocate the wish which one of the paper had expressed, that they have an English style, and that this industry, was of enormous importance, should prosper in the country. They must all agree with him that the best chance of its succeeding, would be if workmen and manufacturers to come to the point, and to act upon the conclusion, that the standards were identical. He did not know how far it was anything so likely to conduce to it, as when a large employer of labour spoke as well had spoken, of the society which came into his purview, the Flint Glass Makers', and when they found that the manufacturer, treating the trade society as an opponent, but full credit for all the good which it could and

He was sure they owed a hearty vote of thanks to Mr. Powell, for the admirable paper he had

read of glass was passed, unanimously, and the day terminated.

## MISCELLANEOUS.

## TECHNICAL COLLEGE.

The first stone of the City and Guilds of London Technical College, Finsbury, a building adjoining the Cowper-street Schools, was laid on Tuesday, 10th inst., by H. R. H. Prince Leopold. The classes of young men, previously held in the schools, were attended in 1880 by 421 students, and related chiefly to applied physics and chemistry. The new college will be a plain building in classical style. It will contain 32 rooms, comprising a large laboratory, two lecture theatres, class rooms fitted with appliances for teaching various branches of physics, chemistry, and mechanics, rooms for drawing, professors' rooms, workshops, an engine room, and clerks' offices. The cost of the building and fittings is estimated at £30,000 or £25,000. The funds have been provided by the City companies and the City of London, and are administered by the City and Guilds of London Institute for the Advancement of Technical Education.

The Lord Chancellor (Lord Selborne), on behalf of the Council of the City and Guilds of London Institute, welcomed his Royal Highness, and said that the institute now conducted local examinations in subjects of 53 industries, and in 85 different places. The number of candidates at the examinations three years ago was 702, last year it was 316, and this year there were 2,401 entries. Through the liberal co-operation of the Royal Commissioners of the Exhibition of 1881, a valuable site of ground at South Kensington had been given, or let at a nominal rent, to the Institute, for the purpose of erecting upon it a central institution, and sufficient funds were already provided to make it certain that it would soon be established. The object of that central institution was to give the highest kinds of instruction necessary to qualify persons to become teachers of the industrial arts and their principles all over the country. The Finsbury College was not to interfere with the necessary training of the factory and the workshop, but it was meant to give artisans that knowledge which would enable them to receive their training in the most intelligent manner. The institution had received from 26 firms connected with the business of cabinet-making and furnishing an application that their trades might be admitted to the benefits of the institution, and it was intended that they should be admitted. The institution held an intermediate place between the central institution at South Kensington and the upper schools, whether technical or middle-class schools, from which the pupils would originally come, and at the Finsbury College they would receive a sound foundation of knowledge for the practice of their different arts and trades.

Prince Leopold having guided the stone into its proper position, said, my Lord Mayor, my Lords, Ladies, and Gentlemen,—I have now had the pleasure of laying the foundation stone of the first technical college ever erected in London. The report presented by the Council of the City and Guilds of London Institute for the Advancement of Technical Education will inform those interested in this most important undertaking of the magnitude of the work, and of the energy and perseverance with which it has hitherto been pursued under somewhat adverse circumstances. The object which the institution has proposed to itself is a truly national and patriotic one. It has proclaimed its determination to enter into a generous rivalry with other countries in those branches of trade and commerce in which one must needs confess that our native industries have, of late years, not taken the position which we, as Englishmen, would wish them to occupy. The old apprenticeship system, whatever its merits may be, and whatever good work it may have

done in the past, is not equal to the exigencies of the present age, and we are beginning to realise that a thorough and liberal system of technical education must be placed within reach of the British artisan, in order to enable him to hold his own against foreign competition; and when this is done, I believe, as I have said on a former occasion, that we need not fear any rivalry in the world.

Mr. F. J. Bramwell, F.R.S., as Chairman of the Executive Committee of the Institute, proposed a vote of thanks to his Royal Highness, which was seconded by Mr. Mundella, M.P., and carried unanimously.

### DOMESTIC SANITATION.

At a meeting of the Ladies' Sanitary Association, held in the Rooms of the Society of Arts on Tuesday, 10th inst., H.R.H. the Princess Christian presented the prizes and certificates adjudged by Dr. B. W. Richardson, F.R.S., to successful candidates in the examinations on the subject of his lectures on Domestic Sanitation.

Dr. Richardson said—The presence of the Princess Christian to distribute the prizes connected with the lately delivered course of lectures to the Ladies' Sanitary Association, makes me recall an incident which, though it occurred long ago, is in some way connected with the present. In the year 1855, when sanitary science was not so popular as it is now, when, in fact, it was an ignored if not a tabooed subject, a young and enthusiastic sanitarian ventured to initiate and edit a new journal called the *Journal of Public Health*. He took great pains to get the best contributors he could, and to make the work as attractive as possible, and spent some time in inventing a motto for the title page. Many of these efforts were successful, and his motto, "*National health is national wealth*" has passed into a proverb. But in other respects his work was a failure; it got no circulation. In despair he was about to give up sanitary labours altogether, when one evening he received a short note from his good friend Sir James Clarke. Sir James in effect wrote, "I send you a hasty line to tell you something that will do you good. I had a conversation to-day with Prince Albert. The Prince has seen your journal, and is pleased with the tone of it. He considers your article on the sanitary condition of the army very useful, and likes your motto, '*National Health*,' &c., extremely. He has directed two copies of the journal to be sent regularly to the Royal Library, and wishes you all success in your work." I can assure you, ladies and gentlemen, that no poor traveller on sandy desert ever drank from spring of fresh water more cheerfully than this sanitarian did from that intelligence, for it came to him, not only as an encouragement from the Prince Consort, but as from a pioneer in sanitary progress, who was one of the first to recognise that a truly healthy nation must be a happy, a contented, and a prosperous nation, and who had practically striven to set the foundations of that health, happiness, content, and prosperity, by showing how to lay them in good and wholesome and beautiful homes for the people. From the time he received the note of Sir James Clarke, this sanitarian never again hesitated. By lectures, by statistics, by argument, and, when the occasion offered for addressing great numbers, by allegory, he tried to teach still that "*national health is national wealth*." And now he has this new recognition, which will always be remembered, that after a quarter of a century, a Royal lady, who is amongst the nearest to the good and illustrious Prince, comes forward to give away the prizes, which completes his latest and, in some degree, most successful effort as a sanitary reformer. The course of lectures which has just closed is one of several courses that have been delivered before the Ladies' Sanitary Association. It was suggested to the Association by

the address I had the honour to speak before Congress of the Sanitary Institute, so ably presided at Exeter by Lord Fortescue, and owing to the energy by which the movement has been carried by the committee, and the unceasing activity of the secretary, Miss Rose Adams, it has been a most fortunate. Nearly three hundred pupils have been regular attendance, and have formed a class, indeed, a real pleasure to instruct. The subjects of food and digestion, of the circulation of the blood, of nutrition, of vital warmth, of breathing, and of the various adaptations to domestic life, have been most carefully discussed and illustrated by the handsome prizes offered by the distinguished in the sanitary cause, Mr. Edwin Chadwick made the work go forward with such energy that no fewer than seventy-five competitors (and gentlemen), with a grand total of over one hundred closely-written competitive papers entered the field in friendly contest. The papers have thus been composed on seventeen subjects submitted for answer, and so excellent are the papers, so clear, so methodical, so exact in adjudication has almost been a penalty. I have all come to me anonymously, marked with a number, so that I am ignorant at this moment the honours are awarded. I wish I could say to everyone, for none are actually unworthy of the honours, while to those who are the recipient of merit is indeed of signal character. The "Chadwick" Prizes, a first of ten, a second of five guineas; a third prize of two guineas Mount-Temple; a fourth prize of one guinea Marshall; a fifth of one guinea, by myself; first-class certificates of merit, sixteen first-class certificates of merit, and nineteen second-class certificates of merit. In commenting, in the briefest, the results of this trial of skill, I will allude to one or two of the most practical. In the essays, certain candidates have evinced knowledge and skill than the rest, but shown that they have a sound knowledge of the subjects, viz., the relative values of the substances of food; the circulation of the blood; the breathing, with the conditions which promote and healthy dwelling; and the management of the room. On the last topic, such thoughtful consideration bestowed that, if I were a sick man, I do not know where I could look for intellectual and skill with so much hope of advantage, as a seventy-five essayists who have answered to me on this all-important domestic accomplishment. Now, my Lord Aberdare, the time has come when to give, those who receive, and those who experience equal delight. Her Royal Highness distribute to the successful candidates their rewards.

Mr. Chadwick, in moving a vote of the Royal Highness, said—It is permitted me to say of thanks to her Royal Highness for the high attendance here to-day, and the high success conferred on our proceedings. In doing so to express the gratification which I feel, by all, as I may presume to take it as a sign of the continued interest bestowed by our friends on sanitary science—the improvement of the people. In reference to it, I had great statement that, if all the owners of cottages in the Empire exercised the same sanitary care that has been exercised on the cottages on her Majesty's estates, the general sickness and death-rate would be reduced one-third; that is to say, it would every third year there were a jubilee, and no deaths. At the first International Sanitary Conference when Royal Princes exhibited chiefly deeds of art, the one object which her Royal Highness had in her sole personal contribution to the Institute

was seconded by Lord Alfred S Churchill,  
dare (the Chairman) responded on behalf  
1.

There seems reason to think that a practical result of the discovery here described will be the use of lamp-black in an articulating photophone, in place of the electrical receiver hitherto employed. It is now definitely established that the colour and the physical condition of the solids operated on determine the intensity of the sonorous effects. The explanation given by Professor Bell is to the following effect:—Lamp-black is a substance which becomes heated by exposure to rays of all refrangibility, and a mass of this substance may be looked upon as a sponge, with its pores filled with air instead of water. When a beam of sunlight falls upon this mass, the particles of lamp-black are heated, and, consequently, expand, causing a contraction of the air spaces or pores among them. Under these circumstances a pulse of air should be expelled, just as water would be squeezed out from a sponge.

The force with which the air is expelled must be greatly increased by the expansion of the air itself, due to contact with the heated particles of lamp-black. The converse process takes place when the light is cut off, the particles become cool and contracted, the air space is enlarged, and, in consequence, a partial vacuum is formed, into which there is a rush of air from the outside. Owing to the great molecular disturbance that takes place in lamp-black, it is imagined that this substance will entirely supersede the costly selenium electric receiver.

Very curious results were obtained in course of experiments with the solar spectrum. Different substances—solids, liquids, and gases—were used as receivers, disclosing the fact that the maximum of sound produced with them varied in point of position on the spectrum in a remarkable manner. With the lamp-black receiver a continuous increase in the loudness of the sound was observed upon moving the receiver gradually from the violet into the ultra red, far out into which the point of maximum sound lay. Beyond this point a slight motion of the receiver caused complete silence, so abrupt was the passage from the maximum sound into its absence. These experiments have led to the construction of a new instrument for use in spectrum analysis. The eye-piece of a spectroscope is removed, and sensitive substances are placed in the focal point of the instrument, behind an opaque diaphragm containing a slit. Those substances are put in communication with the ear by means of a hearing tube, and thus the instrument is converted into a "spectrophone." While it is not claimed that the ear can, for a moment, compete with the eye in the examination of the visible part of the spectrum, in the invisible part beyond the red, where the eye is useless, the ear will be invaluable; and for this reason the "spectrophone" must ever remain an adjunct to the spectroscope, in addition to its having a wide and independent field of usefulness in the investigation of absorption spectra in the ultra red.

#### THE KEELEY MOTOR.

There are few at the present time acquainted with the higher walks of mechanism who have not heard of the "Keeley Motor." Now, what this "motor" is, no person seems to know; what it proposes to do after it has once been brought to a state of completion is really invaluable, *inter alia*, from the charming simplicity with which its claims are put forth, viz., to get an enormous amount of mechanical power from nothing, or at any rate from nothing at all worth speaking of; for instance, a glassful of water to drive a railway train for over a hundred miles. Keeley was confident of his being able to solve the problem, and the stock-holders and stock-dealers equally confident that there was something in it. It is true that it has long been the standing ridicule of mechanics of the every-day school, and for several years reputable journals such as the *Scientific American* have always linked the word "deception" to the usual title of the inchoate power; but what more easy than to persuade moneyed speculators that all great and new discoveries are subject to detraction? Accordingly money has flowed in plentifully, until recently when stock holders began to demand that they must see something, plenty of time having surely elapsed since first the stock was thrown into the market. But as Mr. Keeley retained the "secret" in his own hands, he was master of the situation, and if they would not advance more money it would be their own loss, as his invention was now almost perfected. A "first public exhibition" of the Keeley engine was, however, determined upon, and was given in Philadelphia on the evening of the 22nd April, in presence of a large body of New York men, among whom are some of fairly high social and political standing, but none whose names are recognised as belonging to the world of practical machines. When the visitors were seated, they saw before them a well-polished steel machine composed of tubes and globes. Like a scene connected with con-

juring apparatus, the first act consisted in every cock and tube, ostensibly to show the apparatus was empty. Lights were placed under and the visitors were invited to look into and the various chambers. The performance commenced by one of the company pouring a glass into half-a-dozen funnel-topped tubes, and in twenty-nine seconds after the last drop went in, a pressure was generated sufficient to raise a six-foot (one inch fulcrum), upon which were hung 700 weight. The pressure was asserted to be 15,000 lb. per square inch. Pausing for a moment, I may say that innumerable Englishmen, and also many Americans, are aware that a "Geyser" apparatus has for years, been in London an article of common means of which cold water poured into a vessel the top emerges, after a few seconds, from a spout at the bottom, heated to the boiling point. But Mr. Keeley's visitors on the occasion referred to were not quite aware of what takes place when a liquid is allowed to come into contact with a metallic surface. The vapour said to create the pressure, in the experiment now being described, was passed into a steel cylinder about 30 inches long and 4 inches in diameter, through the centre of which stretched an ordinary piece of piano wire, a means of some mysterious influence exerted by the vibrations of the wire. This vapour was then converted into an engine in another room, to which all the visitors were then invited to move. Here was placed the engine, or piece of mechanism, that at present is considered as indescribable. After the opening cocks, something, that was termed a "spiro" contained in one of the cylinders, or rather the mechanism began to roar, and a shaft of steel with it began to revolve rapidly. The rapid revolutions of the engine were controlled by Mr. Keeley striking an iron disc or drawing a bow over a stretched steel wire. Now, what does all this piece of mechanical legerdemain amount to? An inquiry of the sober, common-sense mechanician who has sought to obtain at headquarters in New York some reliable information concerning this "new power," which he could place before the pages of the *Journal of the Society of Arts*, but has quitted up to the present time in being able to assign a position of reliability or genuineness, notwithstanding that Commander Gorrington and others speak of it as perfectly wonderful.

#### NEW AMMONIA ENGINE.

Different altogether from the "motor" just mentioned is a "low temperature motor," into which what searching examination has just been made by the chief engineer of the Navy Department of the United States of America. This differs *ab initio* from the "Keeley Motor," in that there is no alleged mystery, everything being explainable on scientific principles. Originating in a machine in which ammonia is used as a means of producing ice, experiments have led to the discovery of a motor which, when completed, it is stated, prove of inestimable value. It is being converted into gas under high pressure, and a low temperature has about three times the force of steam. While water requires to be heated to a high degree of heat ere its powers can be put forth, ammonia, on the contrary, puts forth its power at ordinary temperature. The difficulty has now been to get the ammoniacal gas condensed, but this has been overcome on the end of a piston. It is now being put to the test by Chief Engineer Ingham, who is acting in conjunction with Professor John Gamgee, that this has been overcome. In the new ammonia engine is a high pressure boiler where the ammonia is converted into gas by the heat in water of ordinary temperature, and a low-pressure boiler, in

is kept at a considerably less tension than in ; and with which the engine is operated. ng its work, the cooled and shrunken gas and e discharged by an ejector worked by the e same in the high-pressure boiler. This excess ia in the liquid form is pumped from the low- ack to the high-pressure boiler, while the heat is continually being converted into the al work done by the engine. The high of the men engaged in working out this idea, open manner in which they state the whole upon which every action is based, proves to eat a guarantee of the possibility of something being eventually achieved by its agency, for, e "Keeley Motor," there is in the ammonia secresy as regards either principle or mode of

St. April 20th, 1881.

### METEOROLOGICAL SOCIETIES.

subject of Mr. G. J. Symonds's presidential at the last annual general meeting of the logical Society, was "The History of Meteorological Societies—1823 to 1880." The English effort at forming a meteorological x, at any rate, at securing observations made sparable instruments, recorded upon a uniform was made in 1723 by Dr. James Jurin, who a secretary to the Royal Society. In the tical Transactions" for that year will be able Latin address by Dr. Jurin, in which he e nearly all the conditions which we now onal for comparable observations. This appeal led to much being done, and 20 years later, rd, 1744, another attempt was made by Mr taking, F.R.S., who read before the Royal a paper, entitled "Scheme of a Diary of the ; together with Draughts and Descriptions of e subservient thereto." The Royal Society egin their register until 1774, and then they only d it consecutively until 1781, after which they several years to elapse before they again under-

In 1780, the Meteorological Society of the to was formed, and in the following year they ed their observations. The secretary of this in Society died in 1790, and from that time ety languished, and finally became extinct he troubles and wars of the French Revolution. i meeting for the formation of the Meteor- ology of London was held on October 16th, the London Coffee-house, Ludgate-hill, Luke , Thomas Forster, Dr. Clutterbuck, J. G. &c., being among its chief supporters. The anguished soon after its foundation, but was in 1836, and finally died about 1843. Seven rwards the British Meteorological Society led by Dr. Lee, Admiral Smythe, and many pporters of the old society. In 1846, the society a Royal Charter of Incorporation, and, ceasing he Barran Meteorological Society, became the logical Society."

### GENERAL NOTES.

**Engine.**—The following description of a solar given by Mr. G. F. Rodwell, in his report of the e the French Association for the Advancement of e Algeria, in *Nature*:—"In the Agricultural Exhi- of the most interesting machines is the solar engine, of which is placed in the axis of a mirror 14 feet e, and formed of three portions of hollow truncated e to get a close approximation to the parabola. e sun shines a pressure of from three to four

atmospheres is produced in the boiler, and a force of one-horse power is produced through the intervention of an ordinary steam-engine. The mirror is of silvered copper; the boiler is blackened and is surrounded by a glass cylinder, which of course permits the passage of the sun's heat through it, but obstructs its escape after absorption. The whole thing costs 4,000 francs, and it could be used in many countries for at least 200 days in the year.

**Fruits from the West Indies.**—The success which has attended the experimental shipments of ripe fresh fruits from Australia has set the West Indians on their mettle, and several planters have turned their attention to the cultivation of oranges, pine-apples, bananas, and other fruits, especially for shipment to Europe. America has hitherto been the chief customer of the West Indian Islands for fresh fruits, but there is no reason why England should not share in the fruit produce of her nearest tropical colonies. At the present time the trade in pine-apples is pretty well monopolised by the Bahamas, from whence we receive the cheap fruits which are displayed in a more or less damaged condition on the costermongers' barrows in the streets of London during the summer months. But if more care were taken in selecting and packing the fruit, pine-apples might be received in excellent condition from all the West Indian Islands, and not only pine-apples, but bananas and oranges. The greater expense which would be incurred by a little more care in packing the fruit, and the additional cost of freight, would be more than covered by the higher prices which would be realised for ripe oranges, for instance, which could be sold at the time when such a luscious fruit would be most highly appreciated, viz., during the summer months, and at a time when the ordinary supply of European oranges would not be in the market. One enterprising cultivator in Jamaica, who has lately taken to growing pine-apples for export, has realised as much as £60 per acre. The trade in bananas is also increasing, at least, so far as Jamaica is concerned, and last year nearly half a million bunches were exported from that island, valued at over £30,000. In the case of oranges the value exported last year from Jamaica was over £11,000. *Colonies and India.*

**Gum Arabic at Trieste.**—Mr. L. Ordogo, Consul-General of France at Trieste, has furnished, under date of August 10, 1880, some statistics relating to the amount of gum arabic which arrives at Trieste from Africa. The total importation and exportation during the years 1877, 1878, and 1879, was as follows:—

	Importation.	Exportation.
1877 .....	2,686,100 kilos. ..	2,737,800 kilos.
1878 .....	2,726,300 " ..	2,796,400 "
1879 .....	4,638,400 " ..	3,080,900 "

The gums are divided into thirty-two grades, the prices of which vary from about 75 dollars for the best, to as low as 18 dollars per 100 kilos. for the commonest kinds. The available stocks during 1877 amounted to 1,700,000 kilos., but, in 1878, they exceeded 3,600,000 kilos, and even this enormous reserve was hardly sufficient to satisfy the demands from the various markets of Europe. On August 1, 1880, the stock on hand at Trieste was as follows:—

	Kilos.
Arabic .....	287,000
Ghissira .....	52,800
Sennary .....	1,400
Suskin .....	313,000
Gedda .....	79,000
Total .....	838,000

The construction of new routes has rendered the transport of the Suskin gum more easily from its place of origin to the port of debarkation. Owing to the interruption of communication caused by certain rains called "kalis" in Egypt, no arrivals whatever from Suskin reached Trieste during the whole of last October.

**Fruit Gardens of Bohemia.**—The number of fruit trees in Bohemia of all sorts, but chiefly apples, appears, from some recently published statistics, to amount to 14,000,000. Of these, 10,000,000 are in gardens, 1,000,000 in waste lands, and about 2,000,000 on the sides of the public roads. The number of young trees annually planted is about 1,500,000. Between 6,000 and 7,000 miles of road are planted with fruit trees, mostly of the best sorts, and the revenue therefrom is very large. The fruit is largely exported to the north of Germany and Russia.

## MEETINGS OF THE SOCIETY.

## ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MAY 18.—"The Electrical Railway, and the Transmission of Power by Electricity." By ALEXANDER SIEMENS. Dr. SIEMENS, F.R.S., will preside.

## FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 31.—"The Principality of Loo Choo." By Consul JOHN A. GUBBINS.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday evenings, at eight o'clock:—

MAY 26.—"Telegraphic Photography." By SHELFORD BIDWELL. Prof. W. G. ADAMS, F.R.S., will preside.

## INDIAN SECTION.

Friday evenings, at eight o'clock:—

MAY 13.—"Burmah." By General Sir ARTHUR PHAYRE, G.C.M.G., K.C.S.I., C.B. Sir RUTHERFORD ALCOCK, K.C.B., will preside.

Members are requested to notice that it may be necessary to make alterations in the dates of the above papers.

## CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

*Syllabus of the Course.*

## LECTURE I.—MONDAY, MAY 16.

Introductory. Nature of colour vision generally. Solar light—its composition. The prismatic spectrum. Invisibility of certain elements of the spectrum to the colour-blind. Appearance of the combinations of the remaining elements. Varieties and definitions of the resulting colour blindness.

## LECTURE II.—MONDAY, MAY 23.

Mistakes of the colour-blind in daily life. Their methods of endeavouring to counteract the consequences of their defect. Modes of testing for colour blindness. Sources of error in testing. The actual prevalence of the affection in this and other countries, and in different classes of the population.

## LECTURE III.—MONDAY, MAY 30.

Industries chiefly affected by colour blindness—Engine-drivers, pilots, artists, letter-sorters, drapers, painters, &c., &c. Recent legislation affecting colour blindness in America, and urgent need for it in this country. Conclusion.

## ADMISSION TO MEETINGS.

Members have the right of attending all the Society's meetings and lectures. Every Member can admit two friends to the Ordinary and Sectional Meetings, and one friend to the Cantor Lectures. Hooks of tickets for the purpose have been issued to the Members, but admission can also be obtained on the personal introduction of a Member.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 16TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. (Cantor Lectures) Brudenell Carter, "Colour Blindness, and upon Various Industries." (Lecture I.) Institute of Surveyors, 12, Great George-street, 8 p.m. Resumed Discussion on Mr. Paper, "Land Law Reform." Victoria Institute, 7, Adelphi-terrace, W.C. Joseph Fayer, "The Rainfall of India." Social Science Association and Law Amendment Society, 1, Adam-street, Adelphi, W.C., 8 p.m. "A Consolidation of the Acts relating to and Industrial Schools."

TUESDAY, MAY 17TH...National Health Society (of the Society of Arts), 7½ p.m. M. Hellyer, "The Science and Art of Sanitary (Lecture I.) Royal Institution, Albemarle-street, W. Dewar, "The Non-Metallic Elements." Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. John L. Paper, "Torpedo Boats and Light Yacht Speed Steam Navigation." Statistical, Somerset-house-terrace, Strand, Pathological, 53, Berners-street, Oxford 8½ p.m. Zoological, 11, Hanover-square, W., 8½ p.m.

WEDNESDAY, MAY 18TH...SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Mr. Alexander B. Electrical Railway, and the Transmission of Electricity." Meteorological, 25, Great George-street, S.W., 8 p.m. Mr. Richard H. Curtis, "Comparison of Oiler's Anemometers, with Remarks on in General." 2. The Hon. F. A. ## OF THE SOCIETY OF ARTS.

No. 1,487. Vol. XXIX.

TUESDAY, MAY 20, 1881.

*Letters for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CONVERSAZIONE.

Mr. de la Cava's *Conversazione* is fixed to take place at the Kensington Museum (by permission of the Committee of Council) on Thursday, June 2nd. The cards of invitation are now in course of issue.

## CANTOR LECTURES.

Lecture of the fifth Course, on Madness and its Influence upon Various Subjects, was delivered by R. BRUDENELL, M.D., on Monday, 16th inst. The notes will be printed in the *Journal* at the next autumn recess.

## FURNITURE EXHIBITION.

Exhibition of Works of Art applied to Furniture in connection with the Exhibition of Fine Arts at Albert Hall, will be opened to-morrow. The following are the exhibitors:—Mr. Alderson; Mr. Morant, Boyd and Blandford; Messrs. Graham; Gillow and Co.; Holland and Sons; Wright and Mansfield; Messrs. Lock; Gregory and Co.; Shoobredstone, Jeans and Co.; Sidney Phelps; Messrs. S; and the National School of Woodwork. A non-transferable season ticket for the exhibition will be sent to any Member of the Society who may apply for one to the Secretary.

## EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

An examination in London will be held on Friday, the Society's Examiner, at the Society of Arts, 18, John-street, W., during the week commencing on May 20, 1881. Certificates can be obtained on application to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

## APPLIED CHEMISTRY AND PHYSICS SECTION.

Thursday, May 12, 1881; Professor F. A. ABEL, F.R.S., Vice-President of the Society, in the chair. The paper read was on—

## RECENT PROGRESS IN THE MANUFACTURE AND APPLICATIONS OF STEEL.

By Professor A. K. HUNTINGTON,  
King's College, London.

At first sight, the title which I have given the paper I am about to bring before you this evening, might lead some to suppose that it was intended to deal with very recent events, such as might have occurred within the last few months, or say a year. Such anticipations would be fully justified were I to address you on recent progress in the applications of electricity, for this offspring of intellects of our own era makes marvellous progress from day to day, until one feels tempted to concede to it a position in the universe similar to that occupied in the human body by nerve force. In fact, the want of continuity between our nerve system and what we may call that of the world is fast becoming less and less. We can already flash our ideas and our voices to the farthest parts of the earth, and the reproduction of the images of material objects by similar means seems to be in a fair way of accomplishment. But the subject of our attention to-night had its commencement in times so remote as to be far beyond the reach of human record, and its rate of progress may be measured by that of the world itself in the Arts and Sciences.

Improvements in the Arts and Sciences have gradually modified the methods of producing iron and steel; and, in their turn, the Arts and Sciences have felt the re-action; for all improvements in the manufacture of iron and steel have been not so much in the production of a better quality of article, but in the cheapening of production, by the application of the principles indicated by the progress of science, and by the use of superior machinery. The direct result of this cheapening has been to extend the applications of the products in the Arts. To appreciate this, let us glance back, and see by what means steel was produced up to the year 1855, and what were its applications, and then trace out the causes of the changes which have since taken place in these respects.

The discovery of steel appears to have naturally followed that of the means of reducing iron from its ore. In all primitive methods of iron smelting, steel, in more or less quantity, is inevitably produced. Such methods have been carried on in India and Africa from time immemorial to the present day. A similar furnace has, for several centuries, been employed in Catalonia, in Spain. The comparative cheapness of iron manufactured in other countries by improved methods, is, however, rapidly causing this furnace to pass out of use.

I propose now briefly to describe to you the process in the Catalan furnace, as it is called, in the form

into which it last developed in Spain and the South of France, in order that we may clearly understand the essential differences between iron and steel, both as regards their composition and properties, and also the conditions requisite in the production of each.

*Mode of Conducting the Process.*—The ore is crushed by the hammer, and divided by sifting into lumps ("mine") and very coarse powder ("greillade"). The furnace being still red-hot from the last operation, it is filled with charcoal nearly to the twyer, the hearth is then divided at a point about two-thirds distance from the twyer into two parts by a broad shovel; on the blast side a further quantity of charcoal is added, whilst that on the other side having been rammed down firm, ore is added, so as to fill that part of the furnace; on this is placed moistened charcoal dust, except at the top. A good blast is then turned on, and if the whole is in good order, jets of blue flame at once issue from the uncovered portion of the ore. After a few minutes the pressure of the blast is lowered to 1·5 in. of mercury. At intervals during the process—which lasts about six hours—the blast is gradually raised until it reaches about 3 in., the maximum usually employed.

During the whole of the process, at short intervals, "greillade" and charcoal are added, and well moistened with water, to prevent too rapid combustion. After about two hours from the commencement, the wall of "mine," i.e., ore in lumps, is pushed well forward under the twyer, and more "mine" is thrown into the space thus made; this part of the process is also subsequently repeated at intervals, until sufficient has been added to form a lump of iron or *massé* of the required size. From time to time slag is removed by opening the tap-hole. At the completion of the process, a mass of metal is obtained weighing about 3 cwt., which invariably consists partly of soft iron, and partly of steeley iron and steel.

*Reactions in the Furnace.*—We have seen that in the one part of the furnace only charcoal and "greillade" are introduced, and in the other only lumps of ore. That the ore should be in lumps at that part is a very important point, for in this way the hot reducing gas, carbonic oxide (CO), generated by the action of the blast on the charcoal, is able to pass freely through the mass of the ore, the effect of which is that the water of hydration and the moisture are first driven out by the heat, and then the ore having become easily permeable, the carbonic oxide reduces it to metallic iron, thus,  $\text{Fe}_2\text{O}_3 + 3\text{CO} = \text{Fe}_2 + 3\text{CO}_2$ . There are, however, several stages in this reduction, magnetic oxide being first formed thus,  $3\text{Fe}_2\text{O}_3 + \text{CO} = 2\text{Fe}_3\text{O}_4 + \text{CO}_2$ ; and protoxide is next formed before metallic iron is obtained thus,  $2\text{Fe}_3\text{O}_4 + 2\text{CO} = 6\text{FeO} + 2\text{CO}_2$ , and  $6\text{FeO} + 6\text{CO} = 3\text{Fe}_2 + 6\text{CO}_2$ . At the same time that these reactions are going on, the ore has become impregnated with carbon, derived from the decomposition of the gases with which it is charged. That this would be the case, the experiments of Mr. Lowthian Bell and others can leave no manner of doubt.

On the twyer side, where are placed the charcoal and "greillade," the latter, as the charcoal is burnt away, descends rapidly, and, to a considerable extent, doubtless, escapes reduction, for the arrangement of the blast is such that most of the

reducing gas is projected on to the lumps and does not pass up through that portion of the furnace occupied by the charcoal and "greillade," which, besides, are constantly damped. "greillade" is much richer in silica than the larger pieces, from which it results that a quantity of slag will vary with the "greillade" added. It is always very rich in oxide of iron.

Now, what happens in this process may be this: carburised iron is produced by gradual reduction and fusion of the lump, and this, coming in contact at the bottom of the furnace with slag, very rich in oxide of iron, the carbon of the one combines with the oxygen of the other, and the result is that iron containing more or less carbon is produced, according as much or little oxide was present.

The obvious conclusion would be, that the less there was of "greillade" present the more steel would be the iron; in practice this is found to be the case. This circumstance would naturally suggest the total suppression of the "greillade" when it was desired to produce steel. This would however, be impracticable, for it is necessary that some of the oxide of iron should remain unacted in order to flux off the silica, which occurs in a considerable quantity in the ore. In the blast furnace, this difficulty is got over by employing lime; but lime at the temperature of the blast furnace would not produce a sufficiently fluid slag.

All that can be done, then, is to employ the available means to prevent decarburisation. Accordingly we find that when steel is required in addition to using less "greillade," the slag is tapped out more frequently, so that the lump of iron, as it forms, may remain as little as possible in contact with it. The bank of slag exposed for a longer time to the reducing carburising gases, and is pushed more towards the twyer, so as not to become decarburised by the air which has not had time to combine with the carbon of the charcoal. Little manganese should be present. It is found the presence of manganese has a very important influence, which is probably due to its power to replace iron in the slag. A slag containing manganese is more liquid than if it contained iron alone, and, according to François, has not the tendency to cause decarburisation at the temperature of this process.

In order, then, that steel may be produced by this process, every precaution is taken to cause as little decarburisation as possible; the unavoidable presence of oxide of iron in the slag, and the low temperature, effectually preventing the formation of iron; the former, indeed, making it very difficult as we have seen, to obtain steel.

It might be said, why not increase the temperature, so as to obtain a liquid slag without the oxide of iron. If the temperature were increased, cast iron, instead of steel, would be produced, that is exactly how cast iron first came to be obtained in blast furnaces.

I have gone rather fully into this process, because the principle of it is not always well understood. Rightly looked at, it explains how was first obtained, and what the essential conditions are, in the production of steel. When, therefore, we consider the increased size of blast furnaces, and

crease in temperature, cast iron being product, it naturally followed that should be treated with a view to the steel. This was first effected in the and formed an important industry in this, the Tyrol, and other places, which it is still carried on.

It was conducted in a finery, similar to those employed in the production of cast iron and steel are often produced the same finery. This furnace, in form, consists essentially of a shallow hearth, formed of cast-iron plates. The hearth is inclined at an angle of  $10^{\circ}$  and the bottom is kept covered with a layer

of pig iron, a piece of pig iron, weighing from 60 lbs. to 100 lbs., is placed on the hearth, previously heated; the hearth is then filled with burning charcoal; on it is placed the cake produced in the last operation which has been kept hot in burning the back of the furnace. The rehearth is then filled up with charcoal six or seven pieces into which was divided, are placed on the top. As the production of steel, and the that obtained in the last operation, so working it under the hammer, are together. The blast is turned on. The iron forms into a pasty mass; cinder, of iron, produced during the latter preceding operation, is then thrown on a piece of pig-iron, weighing about 100 lbs., and, afterwards, four or five pieces of pig-iron, weighing each about 100 lbs., are added. (Spiegeleisen is cast iron, containing manganese, in this case about 4 per cent.) is found to be too much decarburised, and is added. The cinder is usually about 2 inches or 3 inches above the cake, the excess being tapped off. There are variations of this process, but I have not made the principle clear. In this the Catalan, it is impossible to obtain the same product. The principle in both is the same, viz., decarburisation by oxide of iron in the finery process, in addition to the in the form of cinder and scale produced; the working of the metal under the hammer results from the reheating, which is carried on at the same time. In manganese also plays an important part. I shall see that in every process for the production of steel, manganese is used with great

notable exception—the cementation process is an early method for the production of malleable iron. Accordingly, we find modifications of the methods of producing malleable iron. Accordingly, the introduction of the puddling process, in which malleable iron is produced in a reheat furnace, was soon followed by a similar method in the manufacture of steel.

The principal difference between the finery and the puddling process consists in the use of a reheat furnace, the manipulation of the metal, and the regulation of the temperature being greatly facilitated. The decarburised metal by the addition of oxide of iron

produced during rolling, and partially by the air which enters the furnace as the metal melts slowly down; manganese is added during the process. It is important that the temperature should be kept low. It is difficult to weld this steel perfectly; this is probably due to the temperature at which the steel has to be worked being too low to make the cinder sufficiently liquid to enable it to be squeezed out under the hammer to the same extent that it is in the case of malleable iron. This difficulty has, however, been got over by completely fusing the steel before working it, so as to enable the slag to completely separate. In this form metal manufactured by this process has been largely used by Krupp. This defect is common to all steel which has been produced without fusion.

The same principle as that which regulates the production of steel by the foregoing methods is taken advantage of in the Uchatius process, which was patented in 1855.

Pig iron is first granulated by running it while molten into cold water. The granulated metal is then mixed with about 20 per cent. of roasted spathic ore, crushed fine; the mixture, to which a little flux has been added, if necessary, is then fused in clay crucibles. If very soft steel is required, some wrought-iron scrap is added.

Lastly, in this category we have a process which consists in heating cast iron, but not so as to soften it, in oxide of iron, in the form of ore or iron scale. In this way partial, or even total, decarburisation of the metal can be produced at will.

So far we have seen, then, that the difference between iron and steel is merely one of degree depending on the amount of carburisation. The methods we have considered, in fact, are only modifications of those practised for the production of malleable iron.

We will now pass to the brief consideration of the different methods of procedure for the production of steel, which, however, I think I shall be able to show naturally resulted from the observation of phenomena occurring in the first process we have had under consideration.

These processes have for their object to impart a certain amount of carbon to malleable iron. The Hindoos have practised one of them from time immemorial. They place in unbaked clay crucibles of the capacity of a pint, a piece of malleable iron, and some chopped wood, and a few leaves of certain plants; the top of the crucible is then closed with clay, and the whole well dried near a fire. A number of these crucibles are then strongly heated for about four hours in a cavity in the ground, by means of charcoal and a blast of air forced in by bellows. There is some reason to believe that an excess of carbon, over that required to produce the hardest steel, has to be added, in order to fuse the metal at the temperature which can be commanded in these furnaces. Before being drawn out into bars, the cakes of metal obtained in this way are exposed in a charcoal fire during several hours, to a temperature a little below their melting point, the blast of air playing upon them during the time. The object of this is, doubtless, to remove the excess of carbon.

In 1800 a patent was taken out by David Mushet, for a process in every respect analogous to that just referred to. He appears, however, to

have applied it to the manufacture of a metal low in carbon, and therefore intermediate between iron and steel, partaking in a certain degree of the properties of both, corresponding, in fact, to what we have referred to as *steely iron*. Since this metal must have been in a state of fusion, Mushet must have brought to bear upon it a very high temperature. The manufacture was conducted in crucibles.

In another method referred to by Biringuccio, in 1540, steel is produced by keeping malleable iron in molten cast iron until it became pasty, and on examination was found to possess the properties of steel. In connection with the theory of steel manufacture this process is of great interest. It shows that iron in a strongly-heated condition is capable of absorbing carbon by direct contact, unless we suppose that the carburisation is effected by dissolved gases, which is possible, for Graham and others have proved that iron can occlude gases even when it is in a solid state.

If we admit that the mutual affinity of carbon and iron, is such as to cause them to unite at the temperature of molten cast iron, it is then not difficult to conceive how the whole mass becomes carburised without the intervention of occluded gas. In asking you to concede that the surface of the iron enters into combination with the carbon in this way, I am strictly within fact, as shown by the Hindoo and Mushet processes. A marked case of this kind occurs when sulphur and silver or copper are brought together at the ordinary temperature, combination takes place.

The particles of iron at the surface having taken up carbon, their affinity would be satisfied, but the affinity of the atoms contiguous and beneath would at once come into play, and would only be satisfied by an equal division of the carbon between themselves and those on the surface.

Imagine a man carrying four cannon balls, his strength just sufficing for the task; he encounters an enemy equally strong, but who is unencumbered, and, therefore, in the possession of his whole strength.

For the sake of simplicity, we will call the man carrying the cannon balls A, and the other B. B first applies his whole strength to wrest one ball from A, and succeeds, for the chances are 4 to 1 in his favour, A holding the ball only with a fourth-part of his strength, whereas B applies the whole of his. B then tries to obtain another ball from A, and again succeeds, for the force he applies in relation to the resistance offered by A, is as 3 to 2. A and B are now on an equal footing; each is capable of taking up two more cannon balls, should the opportunity present itself.

Now, let the cannon balls be represented by the carbon atoms, and A and B by the surface and the inner contiguous particles of iron, then the bath of molten cast iron will form a reservoir from which A can re-charge itself. In the mean time other particles, C, will have deprived B of part of its carbon, just as B did A, and B will, therefore, be again in a position to obtain carbon from A.

The same reasoning would apply to each successive layer of metal throughout the mass, that on the surface taking up carbon continuously from the bath of molten metal, until, if the process were continued long enough, the malleable iron would become converted into cast iron of the same com-

position as that in the bath into which would dissolve.

We now come to what is called the *cen* process. It is not known when this process was first used. It was well described by Réaumur in 1722. In this method bars of iron are glowing red heat, surrounded with ch boxes, into which the air is prevented from entering. The operation lasts from seven to according to the quality of steel required; bars are never uniformly carburised, and they contain cinder, as the metal has not been fused. The process had been a long time however, before it occurred to any one to steel and make it homogeneous. This was done by Huntsman, about 1760. It was the first time that steel had ever been intentionally obtained in a molten state, unless we except the Hindoo method, but the fused product in that case was too highly carburised to constitute steel. I have already premised that the addition of carbon to malleable iron, in order to produce steel, from the observation of what took place in the processes first described. It was, in fact, a matter of common observation that iron, no whether solid or molten, kept in contact with carbon, became more or less *steely*. It was more natural then than to endeavour to produce steel directly in this way?

By all the processes we have so far mentioned, good steel could be produced, but only in small quantity and at great expense. The application of steel were, in consequence, very limited; practically, its use was confined to implements requiring a cutting edge.

In 1845, Heath patented a process which it been successful, would have given him the means of producing steel in quantity. He proposed to melt scrap iron in a bath of molten pig iron in a reverberatory furnace heated by jets of gas. There were two conditions wanting in this process, which caused it to be a failure, viz., a sufficiently high temperature and the power to easily regulate the character of the gases employed. Nevertheless, in this suggestion is to be found the germ of one of the two most important processes of the present day. By the foregoing remarks I intend to imply that the idea of mixing wrought and cast iron together to produce steel was suggested by Heath. On the contrary, as we have seen, this idea was a very old one. In 1722, Réaumur tells us that he succeeded in making steel in a common forge in this way. As far as we are aware, however, Heath was the first to suggest the use of a reverberatory furnace and gas for the purpose, and that is the important point.

It may here be pointed out, that the manufacture of steel by this method does not depend on any means entirely on the adjustment of the relative proportions of wrought iron and pig iron. It appears sometimes to be thought by the specially acquainted with the process, that a good deal of oxidation going on during the operation, which results in the elimination of an equivalent proportion of carbon from the pig iron.

The dominant idea in treating cast iron had always been to refine the metal by the exclusion of atmospheric air, and this was effected by a current of air to impinge upon the surface of the metal, by means either of blowing apparatus

drawing action of a chimney stack. What more real than that it should occur to someone to use iron by blowing air into it, instead of merely on its surface? We find that this idea did actually occur to several persons, widely separated, in the year 1855. It is a noteworthy fact that a large number of what we call discoveries or inventions are made simultaneously and independently in different parts of the world by people who originally had probably never heard of one another.

It would seem as if the records of observations inscribed in men's minds, and in books, until they are naturally pointed to certain conclusions, by a man who follows up these conclusions, and applies them in practice, is not always the one who perceived them. To carry out what appears to be world at large as new ideas, requires great length of purpose, and such a combination of circumstances as to afford an opportunity.

In this year (1855), a patent was taken out by a Gilbert Martien, for refining iron, by forcing through it as it flowed from the blast furnace spouts, along runners, to the puddling furnace. This conception was a very important one in the sense that had not others been working in exactly the same direction the same time, it would probably have assisted in working out the problem involved. The process, as detailed in the patent, was impracticable, and shows internal evidence of not having been worked out on a manufacturing scale.

Just after this patent was taken out, we find George Parry, of the Ebbw Vale Works, making an experiment of forcing air through molten iron, on the bed of a reverberatory furnace, by means of perforated pipes imbedded in the fire-bottom. Vigorous action is stated to have taken place, but, unfortunately for the experimenters, the metal, through an accident, escaped from the furnace, and the further trial of the process was discouraged by the managing director. There can be no manner of doubt that had this experiment been continued, very important results would have ensued. As the Ebbw Vale Company

bought Martien's patent rights, it would appear that their experiments were really based on his idea. Of this I am not, however, certain, as I am not aware of the date at which they made the change.

Two or three months after these experiments, George Bessemer took out his now celebrated patent for the production of cast steel, by blowing through molten cast iron; it should be clearly in his mind that he had been, for a considerable time, previously engaged on experiments on the same object.

Whether Bessemer originally started with the idea of refining pig ready for puddling, and, in the course of his experiments, made the discovery that the action of the oxygen of the air on the carbon of the pig iron, such an enormous heat was produced that the resultant iron was obtained in a molten state—a thing never before accomplished—we do not know. The only alternative is that he arrived at the same conclusion, by inductive reasoning, which, all things considered, is very probable.

Bessemer first carried out his process in crucibles, and in furnaces and arranged so that the contents could be tapped from the bottom into moulds.

Steam or air, either separately or together, and by preference raised to a high temperature, was forced down into the crucible through a pipe. The patent goes on to state that steam cools the metal, but air causes a rapid increase in its temperature, and it passes from a red to an intense white heat.

It was, and still is, to a less extent, an infatuation of patentees, to employ steam in the place of air. Bessemer soon discovered the essential difference which exists in practice though not realised by the excited imaginations of the majority of would-be inventors. Bessemer at first used extraneous heat to start the process, if not, indeed, during its progress, which shows that he was not then aware that the heat created by merely blowing in air would be sufficient.

In his next patent taken out shortly after, however, he dispenses with the furnace round the crucible, and instead of tapping the crucible from the bottom, he mounted it on trunnions, and by tipping it up by machinery, poured the contents from the mouth. This apparatus, devised by Bessemer, is essentially the same as that used at the present day. The way in which he worked out the process in every detail to a grand practical success in such a short space of time, shows him to have been possessed of a mind of great powers of conception. Having the facts before him, he drew the right conclusions from them with unerring judgment, and from one experiment passed to another suggested by it, until with indomitable perseverance he succeeded in bringing about greater progress in the manufacture of steel in a few months than had occurred in centuries before.

It was very soon found that to produce steel by this process which would work properly, manganese, if not originally present, would have to be added. In the absence of manganese, sulphur and oxygen, in anything more than very minute quantities, makes the steel crumble when worked at a red heat; it is said to be "red short." In the case of the oxygen, the manganese combines with it, and passes it into the slag; but, with sulphur, the reaction is different; its injurious effect is simply counteracted by the manganese; it is not removed from the steel.

At first manganese was only employed in the form of spiegel-eisen—a variety of cast iron, containing manganese. The use of this substance was first suggested by Robert Mushet. When, however, it was attempted to produce very soft steels, a practical difficulty arose. If sufficient spiegel was added to impart the requisite quantity of manganese, then too much carbon would have been introduced. This ended in attempts being made to produce spiegel richer in manganese. By suitably adjusting the conditions in the blast furnace, this was soon easily accomplished; and instead of spiegel containing less than 10 per cent. manganese, a 20 per cent. spiegel was produced.

At the suggestion of Bessemer, attempts were made to obtain a still richer alloy. This was accomplished by reducing rich ores of manganese with cast iron in crucibles or in a reverberatory furnace. These richer alloys are known by the name of ferro-manganese. They are employed with great advantage when very mild steel is being manufactured.

By adding at the end of the process a known quantity of spiegel or ferro-manganese, containing a known quantity of carbon, steel of any required hardness could be obtained. There was but one important drawback to the Bessemer process, and that was that phosphorus was not in the least degree eliminated by it; consequently, only the best ores could be employed, which considerably increased the cost of production over that which it would otherwise have been. I will refer to that point again presently.

The year which saw the birth of the Bessemer process was doubly remarkable, for it was at that time that the regenerative system of heating was first introduced by Dr. Siemens. Nothing can be simpler than the principle involved in this method, yet it was destined to play a most important part in the progress of the arts. The idea was to store up the heat escaping in the waste gases from furnaces, and to employ it to raise the temperature of the gas and air previous to their combustion in the furnace. This was accomplished by causing the spent gases to pass through two chambers filled with loose brickwork. When these chambers have become heated to a high temperature, the waste gases are made to pass through two other similar chambers, and the air and gas necessary for combustion in the furnace are caused to pass through the highly-heated regenerators. By causing the ingoing gases to pass alternately, at suitable intervals of time, through each pair of regenerators, a very high and, at the same time, uniform temperature can be obtained in the furnace, without any greater consumption of fuel than in the older methods. The success of this process depended entirely on the fuel being first converted into a combustible gas. This was done in a chamber to which only sufficient air is admitted to convert the carbon into carbonic oxide, which is then conducted by tubes to one of the regenerators to be heated, and thence to the furnace, where, coming in contact with air which has been passed through the other regenerator, it burns, giving out intense heat. It is at once apparent that we have here the very conditions which were wanting to make successful the process patented by Heath in 1845, for not only we have the high temperature which could not then be obtained, but it has become easy to create at will, by regulating the relative proportions of combustible gas and air, either an oxidising, a reducing, or a neutral flame.

There are two methods now in use for the production of steel in the reverberatory furnace or open-hearth as it is called. In France, pig iron and scrap steel are fused together; in England, pig iron is decarburised by means of iron ore, some scrap, however, being generally added for the sake of utilising it. As in the Bessemer process, the necessary amount of carbon is imparted to the metal by the means of spiegeleisen or ferro-manganese. This process has been largely employed for the production of ship and boiler plates. It has the great advantage that the metal can be kept fluid on the hearth, and its composition adjusted until it is exactly that required.

In 1876, a patent was taken out by M. Pernot, in which it was proposed to produce steel on an open-hearth furnace with a revolving bed, inclined

at an angle of  $5^{\circ}$  or  $6^{\circ}$  to the vertical. Pig iron previously heated to redness is placed in the bed of the furnace and covered with scrap steel. The bed of the furnace is then made to revolve slowly, the pig gradually melts, and the scrap is alternately exposed to the strong heat of the flame, and then dipped under the molten pig iron. In this way the fusion is very rapid comparatively, the whole mass becoming fluid in about two hours. The process is then completed in the ordinary way. When repairs are necessary, the bed on its carriage is drawn out.

In practice, it is found that these furnaces require very frequent repairing. With the view to make this easier, M. Pernot has arranged a movable roof, which has besides the additional advantage of reducing somewhat the strain on the structure occasioned by such great variations in temperature. M. Pernot informs me that he has just taken out a patent for an arrangement of his furnace by means of which he can employ gas under pressure, and that within the last few months he has obtained by this means results which have never been equalled before. He states that, in a seven-ton furnace, he has obtained five charges in twenty-four hours. This, at any rate, contrasts favourably with the figures given by Hackney, in 1875. He says five charges, of about four and a-half tons each, are got out in each twenty-four hours; the coal used being about eight to eight and a-half cwt. per ton of steel. The averages obtained with furnaces of similar design, and working under similar conditions, but with fixed beds, he states to have been just about half, and the coal used per ton of steel to have been eighteen cwt. Mr. Holley, of New York, has recently stated that they are getting with the ordinary Pernot furnace a seventeen-ton charge in six and a-half hours, all cold stock, except five tons pre-heated scrap.

The Steel Company of Scotland tried the Pernot system and abandoned it. They appear to have come to the conclusion that, owing to the great trouble and expense in keeping the furnaces in repair, the system possessed no special advantage over the ordinary Siemens furnace. If I am not mistaken, however, the Steel Company of Scotland were using these furnaces for soft steel for ship plates, whereas, in the instances referred to, the steel was being manufactured. This is an important difference, the temperature in the former case requiring to be much higher than in the latter, the carbon being less, and the metal, therefore, more infusible; consequently, the wear and attendant expenses would be proportionately greater. Be that as it may, it is beyond dispute that this system has achieved a considerable measure of success abroad, which will probably increase, as modifications, such as I have referred to, are gradually effected to reduce wear and tear, and facilitate repairs.

We now come to the Ponsard furnace. It aims at combining the advantages of the Bessemer and open-hearth processes. The furnace is so arranged that, by giving it a half revolution on its oblique axis, the troyer which it is supplied may be brought either below or above the surface of the bath of metal. By these means the metal can be rapidly decarburised nearly entirely, as in the Bessemer converter, and

moving the tuyers from beneath the al adjustment of the carbon can be the Siemens process. The only difficulty in working out this idea to a mass appears to be the rapid destruction of the lining. This obstacle is certainly a very great one, and it may possibly be found insur-

mountable. It may be remarked that some firms in England, indeed, too, claim to be able to produce steel of any required composition with equal exactness by the Siemens process as by the Bessemer. There can be no doubt that much can be done in this Bessemer process where the work is properly and carefully carried on.

Regarding the fact that phosphorus contained in the ordinary Bessemer conversions quantities of steel have been produced by this process, and within the last two or three years have been devised by which this steel-makers has been overcome. It is known as the Thomas-Gilchrist process.

In the ordinary Bessemer converter the lining is magnesite, a siliceous material. Now, having a greater affinity for oxide of iron than lime has, consequently, so long as free phosphoric acid cannot remain in the converter with oxide of iron; whilst, then, the converter was of silica, it is sufficiently strong; phosphoric acid could never be

removed at once say, why line the converter with a non-oxidizable substance? The answer is, the Bessemer process was known, and the reason why phosphoric acid was not removed was not general.

In the state of things when Messrs. Thomas and Gilchrist commenced their experiments, the object they had in view was to substitute for magnesite a basic material, such as silica, which they had to contend with was lining which would hold together. Through failures and much patient labour, it has been found which fulfils the necessary conditions. This material is magnesian limestone; and mixing it with pitch, bricks can be made which, after burning, are very refractory. Lining the converter it was impossible to get the bricks satisfactorily together; they were a good deal curved in baking, and the cementing material is blown out by the molten metal. In order to overcome this difficulty, the converters have been lined with the material in, and then drying in stoves the various pieces of which the lining is composed. This method has proved successful.

By this process, by judicious treatment, we may convert the phosphorus into a friend.

In the Siemens process, it is essential that about 2 per cent. of silicon should be present, for it is, due to the presence of silicon, that a high temperature can be obtained. In the Bessemer process, the less silicon there is the more it destroys the lining by fluxing. It is not that the phosphorus befriends the lining, so, is capable of producing a high temperature by combining with oxygen; and that

being the case, it becomes possible to work with about half the silicon necessary in the acid process, which practically means that we may employ a much lower grade of iron; for the lower the grade of iron, the smaller will be the amount of silicon in it.

So appreciated has this hitherto despised substance become, that it is actually the practice to put back into the blast furnace a great part of the slag from the converter, in order to increase the amount of phosphorus in the pig iron, subsequently to be converted into steel.

There is, however, a limit to the lowness of grade of iron which can be used, for, although the silicon decreases, the sulphur increases, and only about half the sulphur present in the pig iron can be removed in the converter. One-tenth per cent. of sulphur suffices to prevent steel from rolling in a sound condition. As I have already pointed out, the way to counteract the influence of sulphur is to employ manganese in sufficient quantity, but this is not without a drawback, for manganese is expensive.

In working out this process, much difficulty was at first experienced, owing to the mouth of the converter getting gobbled up, that is to say, stopped by projected slag. The basic slag, consisting as it does principally of lime, is very pasty. This inconvenience has been successfully got over by employing converters of the form shown on the diagram. It was predicted by many, that the slag and metal would be thrown out of the mouth of this form of converter; but that has not been the case, and it is not improbable that eventually this shaped vessel will be universally adopted for both the acid and the basic processes. Such is already the case at Messrs. Bolckow, Vaughan and Co.'s works, where, under the intelligent and persevering guidance of Mr. Windsor Richards, the basic process has first been made a commercial success in this country.

One word as regards the silicon, which, we have seen, is useful as a combustible in the Bessemer process. This substance produces both red and cold shortness in steel, which has to be worked, if present, in even so small a quantity as two-tenths per cent. But in the production of sound steel castings, it has been found to exert a very beneficial influence by preventing the metal from becoming honey-combed by escaping gases while solidifying. It exerts its influence by combining with oxygen, which would otherwise unite itself to carbon, and form a gaseous compound; the silica thus produced passes rapidly into the slag in combination with manganese, which is introduced at the same time as the silicon in an alloy containing them both.

In consequence of the extremely high temperature which we can command, either in the Bessemer or open-hearth processes, it is possible to obtain in a molten state metal practically free from carbon, or containing carbon to any required amount. It is sufficiently obvious that, having regard to the original and commonly understood meaning of the word steel, some other name should, strictly speaking, be applied to all metal manufactured by these processes, which cannot be hardened and tempered. In practice, however, there are many obstacles in the way of this being done, and it has become customary to designate by the term steel all the

metal which has been produced in a molten condition by the Bessemer or open-hearth furnaces.

It thus has resulted that we speak of steel ships, steel boilers, and steel rails. The metal of which ship plates are made contains about  $\frac{1}{100}$ th per cent. of carbon, that for boilers about  $\frac{1}{50}$ ths, while rails usually have about  $\frac{1}{25}$ ths. The first and the second could not be appreciably hardened, and the third is considerably below what would formerly have been considered steel.

Although, then, metal possessing the true characteristics of steel can be made by these processes, yet that which is ordinarily made is not steel, but a metal called into existence by our recently acquired power of obtaining an extremely high temperature.

This new metal, as we may fairly call it, has properties far excelling those of wrought iron, and it has only been a question of time to make this universally felt.

At the present moment new iron rails are things of the past, and wooden sleepers have begun to follow in their wake, it having become apparent to all that our new metal will be an economical substitute. So with ships, the wooden walls of old England are no more. Steel has not only supplemented wrought iron where it was used, but the wood also.

At present there is but one sound reason why steel should not universally replace iron with advantage, and that is, that in some cases it is cheaper to employ iron. Statistics show us that the enormous quantities of steel now manufactured have but little, if at all, affected the production of wrought iron. It is, however, I am convinced, but a question of time. When the day comes, and every day brings us nearer to it, when steel will be manufactured as cheaply as iron, then will wrought iron be a thing of the past amongst the great civilised nations.

One word as regards the employment of steel made by these modern methods for cutlery. Cutlery manufacturers would tell you that it is useless for the purpose; nevertheless, on the Continent, it is very largely used, and in this country to a considerable extent. I do not hesitate to assert that, with suitable ores and proper care in the manufacture, steel well suited for cutlery can be made both in the open-hearth and the converter. The essential in the ore is that it should not contain phosphorus; with but a trace of phosphorus present, a good cutting edge could never be obtained.

I have endeavoured to show you this evening in what progress has really consisted, and how it has been brought about. If we glance back for a moment, we see that the open-hearth processes embody the same principle as the first process by which steel was produced, viz., the mutual action of carburised iron and oxide of iron on one another, and the Bessemer process is, after all, though a splendid offspring, only the natural descendant of the finery process, the origin of which, as we have seen, was due to modifications in the primitive blast furnaces. There is perfect continuity throughout, and, after all, what more natural? Progress in the art of manufacturing steel has been the joint work of the scientific chemist and the engineer. As in the past, so in the future, success will depend upon these two elements working harmoniously together.

## DISCUSSION.

Mr. Michael Scott remarked that, within the lessor Huntington had given himself, they could have had a more complete sketch of structure. He would venture to say, with regard to the Bessemer process, that as James Watt left the steam practically perfect, so Mr. Bessemer deserves having left, not only his process practically perfect, but all the apparatus required in connection with it were even now reverting to some of his elements of machinery, finding they were better simple than those which had since been applied. With respect to the use of manganese rejected to as being expensive, but he thought another and still more important reason why it was used in moderation. Dr. Siemens, on one occasion mentioned it very properly as being, like charcoal, that covered a multitude of evils. But it covered the evils, and he had reason to believe not remove them. Not very long ago, he showed specimens of steel which had been exposed to an atmosphere for two or three months, and it was something perfectly alarming. He made with respect to the composition of the metal, as far as he could find which could account for its excessive dose of manganese. Manganese had been useful, and it was very important, but it had been rather too great an extent. With regard to the Bessemer and Siemens processes, they had not yet been very successful in England, where the two great processes were preferred. One advantage claimed was that the time would be saved for producing a charge of steel. No doubt, it would produce steel in less time; but, on the other hand, the simple furnace shown in the diagram, for the Bessemer process, was still supposed to be the best for producing the Bessemer process, he had heard of the very highest quality produced by it. If as the reader of the paper had said, that steel produced for cutlery or for any other purpose it did require very careful attention. At the Bessemer process seemed to have taken the place of the rail trade, and the Siemens process the place of the plate trade, when the amount of carbon was extremely low and the tests extremely high. Savings had been made as to the recent improvements in steel, the progress had been so rapid that only a question of years or even months, but of weeks and days. During the recent meeting of the Iron and Steel Institute, in London, some of the startling character had been brought forward that those interested in the subject require their information up to the latest possible reference had been made to the diagram of which he believed represented Dr. Siemens' improvement in gas-producers. Perhaps it might be rather too technical to go into it, but it was understood, it had been a great success. It seemed to have the elements of success in it.

Mr. Shoolbred said he should like to ask Mr. Huntington, who he believed had carried out experiments with regard to this material called steel, to give some information as to its capabilities for constructive purposes. To himself and to many others the branch of the subject was becoming of great importance. The question of the importance of the vast substitution of steel for iron had not been upon, since there was scarcely any branch of engineering which was at present used where steel was not taking its place. On the other hand, instances which had come within his knowledge of structural use, the expense of the construction of steel in the ordinary forms of T, or double T, required for joists and so on, taking its greater strength into consideration.

It proved to be prohibitory. They were told possibly the price might be brought down; but a few days ago he had occasion to ask one of the makers, and he found that such was not the case at present. With regard to the Siemens's regenerative furnace, it might perhaps be interesting to know how very largely they had come into the industrial arts generally; in fact, it was the use of fuel in the gaseous instead of the solid state. A short time ago he had occasion to make some inquiries on that head, and it came out to him that in the year 1879, probably no less than  $3\frac{1}{2}$  million tons of coal in the United Kingdom were converted into gaseous fuel, by means of this regenerative furnace, in various branches of industry. That showed how largely the use of gaseous fuel was growing; and not long ago, in that room, there was an interesting discussion on the question of using gaseous fuel in domestic arts, in order to get rid of London fog and smoke.

Mr. F. Maxwell Lyte said it might be interesting to have a discussion on the question of the honey-comb structure which occurred in Bessemer steel castings. This subject had caused a deal of discussion, and yet he never seemed to have been any satisfactory explanation given. It had been said that silicon or silicic acid being added to the metal, caused a decomposition of occluded gases therein contained, but this would not be quite the case. But it seemed to him that the carbon, which was capable of deoxidising silica under certain circumstances, at this high temperature, would have a tendency rather to de-oxidise any slag which might be contained, than to have its oxygen drawn from it, and so to produce a silica which would go into the slag. Was it not at least equally possible under those circumstances where silicon or manganese were added to the metal, that there might be produced a kind of alloy, incapable of occluding gases which would be occluded by a purer iron? They knew that pure metal, silver, for instance, was capable of absorbing oxygen gas, which it would not do when alloyed. Perhaps some gentlemen present who had knowledge on this subject, would be able to throw some light on the question.

Mr. J. S. Jeans said he should like, as one who had given some consideration on the manufacture of steel, to add a few words of congratulation to what had been said on the very excellent paper they had just heard. If there was any defective part about it, it was, perhaps, the absence of any specific information as to the results of the processes which had been described, from a statistical, commercial, and industrial aspects. It was, therefore, interesting, if he mentioned the fact, that about 25 years ago, the total quantity of steel produced in the world was under 100,000 tons.

It was previous to the invention of the Bessemer process. Last year, the total quantity of steel made by the Siemens process and the Bessemer together was over 4,000,000 tons. These figures would convey some idea of the enormous progress which had been made in the interval, and of the great industrial development that these processes had contributed to; about. He did not quite agree with Mr. Kingston, in thinking that the application of steel in the future would be such as to completely displace iron.

It was never wise to prophesy unless you were to be aware of the facts, but, having had occasion recently to inquire into that matter, he found in the six iron-producing countries in the world—Great Britain, the production of the manufactured iron, within the last ten years, increased by 50 per cent. Of course, that increase was nothing like commensurate with the increase which had in the same time taken place in the manufacture of steel, but it was sufficient to encourage the idea that for a great many years to come, at all events, manufactured iron

would continue to hold its own. He remembered an ex-president of the Institution of Civil Engineers remarking, not long ago, that, in his opinion, before many years were over, for all purposes except the ordinary working of a blacksmith's forge, steel would be used in place of iron. But they were evidently a long way from that as yet. There was no doubt that, however good the qualities of steel might be, there still remained a great many prejudices to be overcome, and recent occurrences, with which most of them were familiar, were likely to retard its progress considerably in the near future. That these difficulties would ultimately be surmounted nobody would for a moment doubt, but, at the same time, there could be no question that a great deal yet remained to be accomplished by the chemist, the metallurgist, and the engineer, before they found a metal which for all purposes, and under all circumstances, was perfectly trustworthy. He should have been glad if the Professor had shown amongst the many interesting diagrams illustrating his paper the fixed converter, which was adopted at Götte, in Sweden, at a very early stage of the Bessemer process. He believed that there were still in operation in Sweden some fixed converters, and that on account of the great purity of the pig iron used in that country, Bessemer steel was there made without the use of manganese. They were given to understand, by no less an authority than Dr. Siemens, that it was quite within the bounds of possibility, if not already an accomplished fact, that very good steel, even the best, might ultimately be made entirely without manganese, which Dr. Siemens had described as being simply a cloak for imperfections. In the Bessemer process, however, there was no doubt that a great deal remained to be accomplished before that was attained. He should also like to hear some details concerning the manufacture of puddled steel. Even to the present day that was a considerable industry in some parts of Germany, and also in Austria and France, though he was not aware that any puddled steel was now made in this country. It was, of course, not employed to anything like the same extent as the steel made by the Bessemer and open-hearth processes, which, for all practical purposes, might be regarded as the only two processes of the future. It was rather largely due to the failure that took place in connection with the application of puddled steel to ship building, that steel had not been sooner used for that purpose. Some thirty years ago a boat was built for Dr. Livingstone of puddled steel, and the Doctor sent an account of the results obtained to the Society. He found, as might have been expected from the process of manufacture, that it was a material more akin to wrought iron, laminated and heterogeneous, than to the homogeneous ingot metal with which they were now familiar, and the results of its application did not realise expectations.

Mr. Scott said there were essential differences between steel and iron. Steel was a more obdurate metal to work, and, consequently, could not be worked so cheaply as iron. In addition to that there were other considerations; steel shafting running in iron was said to cut into it; therefore there would always be disadvantages connected with its use for some purposes.

Mr. Clements, with regard to a remark made that steel would eventually be used for almost every purpose for which iron was used, said he thought that in the construction of roof trusses, cast iron would continue to be used, perhaps for ever, where there were strains of compression. He did not know exactly what the compression of steel was, but he knew the force of compression of cast iron was very great indeed. Malleable iron, cast iron, and steel, each had qualities of its own, and would be used for special purposes. He believed the Bessemer steel was very well suited for ordinary purposes, for rails and

other forms in which steel was required in the form of mass, and that Siemens's steel was more adapted for plates. With regard to honey-combing, he thought that was produced from the condensation of occluded gas, because there was no doubt that when metals were in a heated state, carbonic anhydride and oxide were present, and as the metal cooled, the gas would also cool and leave vacant spaces. The same thing was found to occur on a large scale in nature, in minerals thrown out by volcanoes. The Thomas-Gilchrist process appeared to be the greatest discovery lately made for removing the phosphorus from the steel, as made in the Bessemer or other processes. It seemed to him that there were now few discoveries yet to be made with regard to the manufacture of steel, which had arrived almost at a state of perfection, and that in the future the perfection of the metal would be more due to manipulative processes by which small quantities of impurities might be got rid of.

Mr. Joseph Gordon said, with regard to the observation made about bringing the price of iron and steel more nearly together, from what the president of the Iron and Steel Institute stated last week, it would be confessed that the prices, as far as rail metal went, were as nearly as possible together now. Taking into consideration the difference made in the tests of iron and steel plates in ship building, he did not think consumers could very well ask steel-makers to come down to the extremely low prices before paid for ordinary iron plates. In that direction, he did not think any *reprochement* could be expected, though he trusted it would be possible to reduce the absolute price of steel in future, when the commoner ones which were found in England could be used with the expensive ones got from abroad.

Professor Huntington, in reply to Mr. Scott, said that, as regards manganese, the same remark would apply to it as to anything else, it was possible to have too much of it. If you found metal which was imperfect, which, on investigation, contained too much manganese, it was not a thing to be surprised at, when you remembered manganese was used in every process by which it was produced. Manganese was used in every process in the production of steel. It was used equally in the crucible process, by which the finest cutlery ever produced was manufactured, and in the Bessemer and every other process. Unless Mr. Scott could suggest some means of getting good steel without manganese, he feared they must continue to use it. With regard to the Ponsard and Pernot furnaces, he brought them forward because the paper was to be on the recent processes in the manufacture of steel, and they might fairly look upon them as being at any rate in the direction of progress. It was impossible to say until a process had been in use some years that it was a commercial success; there were many difficulties to be overcome which required a considerable amount of time, and an expenditure of a great deal of brain power. It required hundreds or thousands of men to be working at a process before it was brought to perfection. These processes, to his mind, had certain portions about them which might ultimately cause them to be successful. Beyond that neither he nor anyone else could speak with certainty. With regard to the use of steel for constructive purposes, no doubt it possessed very great advantages, and like everything else new, required to be studied and understood. In order to use steel satisfactorily, it was necessary that the architect should know something of the properties of the metal he was dealing with, and adjust the proportions of the metal in his structure accordingly. He had not gone far into the question, but from what he understood generally there could be little doubt that steel for the purposes of construction should undergo some modification in form, the properties of the metal being difficult to those of wrought iron. If those who were engaged in the arts of construction would give the metal a little attention, he

thought a large amount of good would result. It was sufficient simply to reduce the section in all very complicated pieces of metal work. As regards honey-combing, he had attempted to explain what was considered to be the cause of the removal of honey-combing as found by those who had experienced the subject. As regards the alloy which Mr. Lytle had suggested as a cause of the removal of honey-combing, he could not agree because he saw no reason to suppose that an alloy occluded gas, when a metal would, because from the experiments of Graham and many others that all metal occluded gas, in fact, all fluids, even the bottle of water before him, if frozen, would show a mass of bubbles of air trapped. Fluids took up gas, and as the pressure of the temperature changed, so would a given amount of gas be occluded, or given off. Mr. Lytle had rather taken him to task for not giving statistics, but he could only say that he had not the hour allotted to him, and when he had time to do that much, he felt he should have exceeded his duty to write more. There were many other matters he would like to have mentioned, but it would have necessitated detaining the meeting for a week. The questions mentioned by Mr. Jeans were no doubt interesting, and could be found by anybody on referring to the proceedings of the Iron and Steel Institute. He appeared to be of opinion that manufactured iron would hold its own. He believed it was a question of time, and prices coming down. As improvements were made, time went on the price would come down, and the steel, which he did not think any man competent to say two metals would deny was infinitely superior to iron, would replace it. Although fixed converters held their own in Sweden, wherever new ones were put, similar to that employed in Europe generally was showing that fixed converters were practically things of the past. Mr. Jeans was not quite accurate in referring to the purity of the pig iron used in Sweden, proving the necessity of using the manganese, because it did not contain sufficient for the purpose. He had not to refer to the puddled steel further than he had. He would only say in conclusion, that steel was not absolutely and indisputably superior to iron, and was used for every purpose for which wrought iron was used.

Mr. F. Maxwell Lytle wished to explain, with regard to his previous remark, that they knew that pure metals were capable of dissolving gas to a considerable extent, whereas alloys of those same metals were not. One per cent. of copper would totally prevent silver from dissolving oxygen, which it took up in a very large quantity when in a perfectly pure state. So would one, or even a half per cent. of gold, or lead, by being alloyed in the same manner, so as to prevent from absorbing hydrogen. He only threw out the suggestion whether an alloy being formed between iron and manganese might possibly prevent the escape, or cause the expulsion of the gases, and he thought was worth investigation.

The Chairman said Professor Huntington had given in a most lucid manner, an account of the important points in the steel manufacture. It was impossible to deal, in the space of an hour, with a subject which would fully occupy many lectures, but he was omitting a point here and there which would have been interesting to all. In connection with the subject—honey-combing—for instance, he had not referred to the interesting and important remark made by Sir Joseph Whitworth on the compression of steel, but it was impossible, in the time at his disposal, to have dealt with the whole subject more comprehensively. That steel had made enormous strides they would all admit, but they had much to learn; they were, in fact, not yet quite in accord with each other as to what it

chemical engineers and chemists had engaged on the question of the *l*, and he believed every one would be satisfied with the definition yet. Again, the varieties of steel and the extra-modifications which it underwent on the action of heat under different effects produced by hardening and might be almost said to know gentlemen like Professor Huntington, really and practically with these sublooked with confidence to make additions to the knowledge of the conditions which would insure a cure of steel, and of the proper methods he would conclude by moving a cordial Professor Huntington for the excellent he had brought the subject under their gaze amount of food he had given them

was carried unanimously.

## SECOND ORDINARY MEETING.

May 18th, 1881; F. J. BRAMWELL, R.S., Chairman of the Council, in

candidates were proposed for members of the Society:—

James, Farnley-house, Chelsea, S.W.  
Charles, 10, Henry-street, Carlisle.  
Leon, 14, Augusta-road, Ramsgate.  
Hilton, F.C.S., 36, Rawcliffe-road, on, Liverpool.  
A., Bush-lane, Cannon-street, E.C.  
29, Prince's-gate, S.W.  
Edward Baring, 12, Hyde-park-

candidates were balloted for, and members of the Society:—

ian, 57½, Old Broad-street, E.C.  
Henry Thomas, 66, Prince's-gate,

Capt. Arthur, Ashley Warren, non.  
randreth, 12, Pelham-crescent, South V.

d H., M.A., F.C.S., F.G.S., 23, Chelsea, S.W.

u, Fairlight-villa, Sydenham-road,

ay, F.C.S., 38, Gracechurch-street,

othy, 45, Charles-street, Berkeley-

7, Grey-street, Newcastle-on-Tyne.  
liam, Hartley-grange, Winchfield,

was on—

## WAYS AND TRANSMISSION OF ELECTRICITY.

Alexander Siemens.

ty was first utilised for practical use of producing it precluded its anything but giving signals or delicate apparatus, requiring means to perform their functions; recovery of the dynamo-electric

principle, some fourteen years ago, powerful electric currents have been placed at our disposal, at a cost which enables us to transform into commercial processes a number of experiments which, up to that time, served only as illustrations of scientific lectures.

The machines which have caused this revolution in the application of electricity consist essentially of two parts—the fixed electro-magnets, by which a powerful magnetic field is created, and the revolving armature, which is connected with the commutator. When the machine is in action, the rapid motion of the copper wire through the magnetic field induces an electric current, which leaves the helix by the brushes pressing against the commutator on opposite sides. From the brushes the current passes to the electro-magnets, and afterwards to the outer circuit, where it has to perform the useful work. In traversing the coils of the electro-magnets, it increases the intensity of the magnetic field, which in its turn induces a more powerful current, and this mutual strengthening of current and magnetic field goes on until a balance establishes itself in the manner afterwards described.

The researches of Sir William Thomson, Dr. Hopkinson, Professor Ayrton, and others have proved that such machines, if properly constructed, will render in the form of electrical work up to 90 per cent. of the energy expended upon them in the form of motive power. It may, therefore, be conceded that they are very efficient transformers, and that we can hardly hope to exceed the results already obtained by the best types of dynamo-electric machines. If, instead of using such a machine to generate electricity you send a current into it, the magnetic attraction created between the poles of the electro-magnets and the currents traversing the armature will cause the latter to rotate, and this motion can be communicated to other machinery in the usual ways. A pair of such machines, one for producing electricity and the second for re-transforming the current into motive power, can therefore be utilised for transmitting power to a distance. In order fully to understand the manner in which this transmission is effected, a large number of experiments were made at the works of Messrs. Siemens and Halske, in Berlin, by Dr. Frölich, and the results obtained were laid before the Royal Academy of Science in Berlin by Dr. Werner Siemens on the 18th November, 1880.

The principal conclusions arrived at were the following:—On applying Ohm's law to a magneto-electric machine (a machine with permanent magnets) we find that the strength of current for a given total resistance is—

$$(1.) \quad C = \frac{n \times M \times v}{R}$$

In this formula C signifies the strength of current; *n*, the number of convolutions of wire on the armature; *v*, the number of revolutions per minute; R, the total resistance in circuit; M, the total E.M.F. produced by the permanent magnets and the iron of the armature in one convolution of wire, when *v* = 1; this quantity will afterwards be called "effective magnetism" of the machine.

The same formula holds good for a dynamo-electric machine. In this case, however, the "effective magnetism" (M) depends on the

strength of current (C), and the formula, by substituting  $f(C)$  for  $n(M)$ , becomes—

$$(2.) \quad C = \frac{v f(C)}{R}; \text{ or } \frac{C}{f(C)} = \frac{v}{R}.$$

In the latter form, the very important law is expressed that the strength of the current in a given dynamo-electric machine depends only on the ratio of the number of revolutions per minute to the total resistance in circuit. If we determine, therefore,  $f(C)$  for a machine, we can calculate beforehand the strength of current it will produce with a given number of revolutions in a given resistance.

The first series of experiments was made to test the correctness of this conclusion, and the curves I., II., and III., embody the results obtained by working one of the largest "Siemens" dynamo machine (type D<sub>o</sub>.) through various resistances at different speeds. The total resistance of the machine was, in case (I.), 435 S.U.; in case (II.), 725 S.U.; and, in case (III.), 714 S.U.

By way of comparison, the curve IV. was set out from results published by Messrs. Meyer and Auerbach in "Wiedemann's Annalen," Band 8, p. 494, who had experimented with a "Gramme" dynamo machine. As will be seen, all these curves do not differ materially from a straight line, and, for the limits of practical working, they fully confirm the above theory. There exists, therefore, a curious similarity between magneto-electric and dynamo-electric machines. In both, the strength of current is proportionate to the ratio of revolutions per minute to total resistance, although the magnetism of the magneto machines is a constant quantity, and that of the dynamo machines varies with the strength of current. The important difference between the two kinds of machine is, that magneto machines give a current however slow their motion is, whereas dynamo machines only begin to give a current when the ratio of number of revolutions to total resistance attains a certain magnitude.

The nature of the  $f(C)$  was then further examined, and the influence on the magnitude of the "effective magnetism" of the currents set up in the iron of the armature by its quick rotation in a magnetic field, and by the currents traversing the coils of the armature. The results arrived at are represented by the curves V., VI., VII., for the large Siemens machine, and by the curve VIII. for the Gramme machine referred to above. They show that at first the "effective magnetism" increases in proportion to the increase of current, then it deviates more and more until it very gradually reaches a maximum, and for still more powerful currents it decreases again. The latter peculiarity is to be accounted for by the fact, that the iron bars of the electro-magnet cannot be magnetised beyond a certain point, whereas the diminishing influence of the currents on the magnetism in the iron of the armature increases continually with the strength of these currents. In practical applications such powerful currents are seldom met with, and it will suffice for the present purpose to assume, that the "effective magnetism" gradually approaches a maximum.

When two machines, identical in their construction, are connected to transmit power, the "effective magnetism" in both should be equal, as the same

current circulates through both of the following equations will, therefore, exist the various quantities:—

$$E_1 = n M v_1; E_2 = n M v_2;$$

$$C = \frac{E_1 - E_2}{R} = n M \times \frac{v_1 - v_2}{R}$$

$$W_1 = a \times E_1 \times C = a C^2 R \frac{v_1}{v_1 - v_2}$$

$$W_2 = a \times E_2 \times C = a C^2 R \frac{v_2}{v_1 - v_2}$$

$$H = a \times C^2 \times R; W_1 = H + W_2$$

$$N = \frac{W_1}{W_2} = \frac{v_1}{v_2} = \frac{E_1}{E_2}.$$

In these formulæ the index 1 refers to the machine producing the current, and 2 to the machine giving out the power for electro-motive force;  $n, M, v, R$  the same quantities as before;  $a$  is depending upon the construction of the machine,  $H$  is the heat, generated in the system,  $W_1$  the work expended upon the primary machine,  $W_2$  the work given out by the secondary machine, and  $N$  the useful effect.

In comparing these formulæ with others it is easily seen that they cannot be questioned. This is most conspicuous with the formula

useful effect,  $N = \frac{v_1}{v_2}$ , according to

which the more the velocity of the second machine approaches the velocity of the first machine, whereas actual experiments show that it is a maximum for a certain velocity of the machine, and will decrease for any lesser number of revolutions of the machine. The cause of this discrepancy is the influence of the so-called "Foucault currents" which are set up in the iron of the armatures by the proximity of the powerful magnets.

In the primary machine these currents circulate in the same direction as the currents in the armature, and by way of "effective magnetism," and, consequently,  $E_1, M, F - E_1$ , they increase the work  $W_1$  upon the primary machine. In the secondary machine, however, in which the armature is in the opposite direction, these Foucault currents circulate in the opposite direction to the armature wires, and by thus strengthening the magnetism and the electromotive force they diminish the work  $W_2$ , given out by the secondary machine.

As our machines are supposed to be identical in construction, the following formulae give the relative proportion of the differences relating to the Foucault currents:—

$$M_1 = M - e_1; M_2 = M + e_2;$$

$$c_1 = \frac{M_1 v_1}{u} = \frac{1}{u} \frac{E_1}{n}; c_2 = \frac{M_2 v_2}{u} = \frac{1}{u} \frac{E_2}{n}$$

$M$  signifies the effective magnetism,  $e_1$  and  $e_2$  the Foucault currents existing in the machines;  $c_1$  and  $c_2$ , the strength of the currents;  $u$ , the resistance through which the currents circulate;  $v$  and  $n$ , having the same

and  $\epsilon$  being a constant, depending on action of the machines.

calculate from the above equations the  $E_1$  and  $M_2$ , substituting at the same time

we have:—

$$M(1 - y v_1); M_2 = M(1 + y v_2);$$

the electromotive force of the two

$$= n M_1 v_1 = n M(1 - y v_1) v_1;$$

$$= n M_2 v_2 = n M(1 + y v_2) v_2;$$

us for the current—

$$\frac{E_2}{R} = \frac{n M}{R} [v_1 - v_2 - y(v_1^2 + v_2^2)];$$

the work expended and given out respec-

$$W_1 = an CM_1 v_1 + ac_1 M_1 v_1;$$

$$W_2 = an CM_2 v_2 - ac_2 M_2 v_2;$$

$$\text{substitute } p = \frac{a}{n_2 u};$$

$$a CE_1 + p E_2^2; W_2 = a CE_2 - p E_2^2;$$

$$\frac{W_1}{E_1} = \frac{E_2}{E_1} \left[ 1 - \frac{p}{aC} (E_1 + E_2) \right];$$

$$(E_1 - E_2); F_1 = p E_1^2; F_2 = p E_2^2;$$

$$W_1 = W_2 + H + F_1 + F_2.$$

formulæ the symbols have the same significance before, and  $F_1$  and  $F_2$  signify the work of Foucault currents.

Electrical quantities  $E_1$ ,  $E_2$ , and  $C$  admit of measurement, and by the help of the formulæ, the quantities  $W_1$  and  $W_2$  can be found beforehand, when the constants of the machines are known.

A number of experiments were then made, and all the quantities were measured, and the results were compared with the quantities calculated from the above formulæ, and it was found that they agreed very well. It is hardly to be observed that these formulæ are applicable to all types of dynamo-electric machines, their construction may be, the character of the machine determining the constants.

The idea of utilising these machines for transmitting power presented itself to Dr. Werner Siemens long ago as 1867, when he discussed the Paris Exhibition with other members of the committee.

but the dynamo machine was at that time not sufficiently developed to admit of a practical execution of the idea, and when the more perfect forms were invented electric transmission was not monopolised for a time all the attention was bestowed upon the practical application of the machines.

The efforts which have been made to introduce electric lighting on a large scale, the idea of using the light-giving machines during the day to distribute power, has come to the front as such an application means a further saving of the invested capital, the combination of the dynamo with transmission of power is sure to

be the purpose a central station has to be built in a district, in which powerful steam-engines working on the most economical principle, a number of dynamo machines, which

produce the electric currents. Secondary batteries, similar to those constructed by M. Planté, and improved by M. Faure, may be employed to receive the electricity, and keep it ready for use in the same manner as the gas is stored in large gas-holders, and as accumulators are used in connection with hydraulic machinery.

From the station cast-iron pipes are laid through the streets, similar to those now in use for distributing gas or water, and insulated wires are drawn into them for conveying the currents from the machines to their destination. At convenient intervals the wires are made accessible by so-called "road boxes," inserted in the pipes, from which the connection to houses or lamp-posts can be made. Two separate sets of wires would be required for the lighting and for the transmission of power, the commutators, for directing the currents, being placed in the station; and additional commutators could be fixed in the houses for switching the current from secondary machines to lamps, without communicating with the station.

There is, no doubt, that much has to be learnt before all the details of such a central station, and of a practical system of distribution have been brought to perfection; but there are, nowadays, few obstacles that cannot be surmounted, and even our present knowledge is advanced enough to teach us that there is nothing impossible in the idea sketched out above.

When a certain amount of power has to be transmitted by electricity to the given distance, it is easy to determine, experimentally, what power is required to drive the primary machine, as the exact conditions, under which the trial was conducted, can be readily reproduced in the practical application. In this respect, the transmission of power by electricity possesses a great advantage over the transmission of power by water or air, as the friction and leakage of the pipes, through which the latter have to be conducted, can never be determined in advance. It further has the advantages that the secondary machine works without producing any waste, which has to be disposed of, and that the small size and low weight of the machines obviates the necessity of heavy foundations for them.

In considering the possibility of employing the electric current to distribute power from a central station, the proportion of the power given out by the secondary machine to the power expended upon the primary machine, will not be of that deciding influence, as is generally supposed. Granted even that not more than 45 per cent. of the power expended can be reclaimed, it will still be possible to produce the power required at a cheaper rate, than if each small place had its own steam-engine. For, at the central station, 1 h.p. could be produced by the large steam-engines with about 2½ lbs. of coal, so that 1 h.p. given out by the secondary dynamo machine would be produced by burning 5 lbs. of coal per hour. There are few small steam-engines which will produce a horsepower with that expenditure of fuel, and if we take into account the trouble and risk connected with the running of steam-engines, it may be readily admitted that this loss is no real obstacle to the introduction of the electrical transmission of power. Of still less consequence will this loss be

where waterfalls or other natural forces can be employed to drive the primary machines, in which case the power would cost practically nothing, beyond the interest on the capital and the depreciation of the machines. The applications which it has hitherto found have, to a certain extent, been of a tentative nature only, and on a small scale, but they are nevertheless very instructive, as they show that economical results can be obtained by it.

About three years ago, Sir William Armstrong erected a turbine at his country seat, Craigside, near Newcastle, and drives by it a Siemens dynamo-electric machine, the current of which is conducted to his residence about half a mile distant from the waterfall. In day-time this current transmits the power of the turbine to the house, where it is used for various purposes, and at night it is converted into light by means of "Swan" lamps, of which it works between thirty and forty. This application deserves special mention, because it is one of the earliest examples of transmission of power by electricity for practical and permanent purposes.

In the same way Dr. Siemens utilises some dynamo machines at his country house near Tunbridge-wells, the power to drive the primary machines being, in this case, obtained by means of a Tangye "Soho" steam-engine. The waste steam from the engine is utilised to warm the hot houses, and the gardener attending the houses takes also care of the steam-engine and the dynamo machines driven by it. In this way the cost of fuel and of attendance is reduced to a minimum.

The electric current is utilised during the whole of the night to produce two lights, by the influence of which various fruits and plants are growing; and the current, in daytime, from one machine sets in motion a similar machine, which works the chaffcutter, and some other machinery, at the farm about a quarter of a mile away from the hothouses. The current from the other machine is conducted to the pumping-house, a distance of about half a mile, and the secondary machine there has supplanted a small vertical steam-engine that used to pump the water up to the house. In this case, the return conductor is formed by the wire fence, care being taken to connect the wires from one side to the other of the intervening gates.

By these arrangements, one man at the farm can do the work of three; and, instead of a man having to drive a steam-engine at the pumping-station, to say nothing of transporting coals there, and losing time in getting up steam, he can set the pump in motion without going near the place, an occasional visit only being required for refilling the lubricators.

There are many similar instances, in which it is advantageous to connect a number of small machines, which work at irregular intervals, by means of the electrical transmission of power with one steam-engine, not only when the distance between the machines is considerable, but also when they are comparatively close together.

Several applications of the latter nature have been made at Messrs. Siemens's works at Charlton; among others the apparatus for testing the mechanical strength of cables, is set in motion by a dynamo machine; and a small pump, which keeps the water in circulation in the core-tanks, is driven by another machine. In both cases it would have

been more costly to transmit the necessary power in the usual way by shafts and belting. A few months ago a machine was placed upon a crane on the wharf, and it was found that by its aid could be lifted about 12 feet per minute, and small weights proportionately quicker. It is only to be added, that the crane was not constructed for this purpose, and that the arrangement was made with the view to demonstrate the possibility of working cranes by electricity, than to obtain the best results.

The electrical transmission of power, on account of the compactness of the machines, and the ease with which the conducting cables can be used, is particularly adapted to be used in cases where the driven machinery is erected only for temporary purposes. As an example, it may be mentioned that, when the cable ship *Faraday* was in the works of Messrs. Siemens, the machinery, which the cable is pulled on board, was driven of the time by a dynamo-electric machine.

Another illustration of the same kind was furnished by M. Felix, of Sermaize-les-Bains (France), who worked, in June, 1879, one of Howard's double-furrow ploughs by a Gramme dynamo machine. The motion was conveyed from the electrical machine to a drum, and thence by wire to the plough. There was no stopping of any kind, but the plough did its work steadily digging up the ground to the depth of about 10 inches. In the following year, M. Felix exhibited at the local agricultural exhibition at Bar-le-Duc a plough and a threshing machine, both worked by electrical transmission of power, with success.

As mentioned above, one of the first things done by Dr. Werner Siemens was to employ dynamo-machines for working elevated railroads, but it was only about three years ago that he was induced to take the matter into serious consideration, an owner of a coal mine asking him to design a means to draw the coal waggons in the mine. The motive to draw the coal waggons in the mine was that Messrs. Siemens and Halske exhibited at the Berlin Exhibition, in the summer of 1874, the model of an electric railway, which had been exhibited at Düsseldorf and Brussels, and at present working in the Crystal Palace. The total length of this circular railway was at that time 300 metres, and the gauge one metre. A dynamo machine, mounted on a carriage by itself, acted as locomotive, and the passengers were carried in three carriages, each having seats for six persons. The current was conveyed from the primary machine to a rail laid between the rails on which the carriages run; thence it was taken off by a sliding contact fixed to the machine and sliding on the rail, it returned to the primary machine by the outer rails. When the carriages were prevented from moving, the locomotive exerted a pull of 4 cwt. (200 kilos.) on them; and when the train was in regular motion, the pull varied between 1½ and 1¾ cwt. (70-80 kgr.), which represents a speed was about 10 feet (3 metres) per second, or three-horse power.

Small as the railway was, it clearly demonstrated that such a mode of transport is feasible; and the advantages of having light carriages, of being able to propel them without noise and smoke, led Messrs. Siemens and Halske to lay before the authorities in Berlin a plan to make an elevated railway.

through one of the streets in Berlin, about  $6\frac{1}{2}$  miles (10 kilom.) long. The kerbstones of the street, iron columns, two-channel irons, were to be erected, yards apart, carrying wooden sleepers on which, in their turn, support longitudinal truss-irons to ensure the stability of the structure, truss-irons keep the girders apart, and serve, at the same time, to insulate them from each other. The height, from the level of the street to the top of the girder, is about 14 ft. 6 in. (4.4 m.), and the depth of the girder about 2 ft. 6 in. (0.8 m.). Steel rails are laid on top of the girders, and the rail on one side serves as a return conductor from the primary machine, and the rail and girder form the return wire; in the electrical resistance of the line is a very low figure.

The gauge of the line was to be one metre, and the cars, resembling ordinary tram-cars, were to be 5'5" broad (1.65 m.) and 8 feet high above the rails. The dynamo was placed out of sight, underneath the car, and motion by means of belts to the two wheels, which have to be insulated from each other, the current arrives through one rail, through the machine, and returns by the other as described above.

It was estimated that at which these carriages were intended to run, 30 kilometres (18.6 English miles), and that there were to be supplied for the railway, of which 10 would be in use, and four in reserve, being required to drive the primary machine of each carriage. The cost was carefully estimated, and, as it serves as an indication what such a system may be expected to cost, a short list of the principal items will not be out of

for 10 kilometres ( $6\frac{1}{2}$  miles), elevated railway, single line.

Cost of the line, including 10 stations	£61,000
Cost of the cars, to hold 15 persons each	3,150
Cost of the steam-engine and dynamo-machine	1,950
Cost of the rails	1,185
Cost of the girders	4,500
Cost of the sleepers	715
<b>Total</b>	<b>£72,500</b>

at 11,600 per mile.

The estimate includes the cost of erection of the line and of the station, at which the steam-engine works, together with the necessary stock to protect the rolling stock against the fire when it is not used. The cost of working was calculated to be, for one year:—

<b>Current Expenses.</b>	
Salaries	£2,190
Light and heat	1,110
Water	50
Repairs	80
<b>Total</b>	<b>£3,420</b>

<b>Depreciation and Repairs.</b>	
£500 (railway and buildings)	£1,875
£300 (carriages and machinery)	800
<b>Total</b>	<b>£2,675</b>

<b>Interest on Capital.</b>	
£500	£3,625
<b>Total per annum</b>	<b>£9,720</b>

at 16s. per English mile per day.

The intention was to run about 200 trains per day, and if the charge of 1d. per mile had been made, the £4 6s. per mile could have been earned, if on the average five or six persons had been conveyed in each case. The concession for this railway was not granted, partly because the inhabitants strongly objected to having people looking into their first floor windows, and partly because the Emperor did not wish to see "The Linden," which this electric railway was to cross, disfigured.

Subsequently, Messrs. Siemens and Halske obtained permission to build a railway on the ground level from Lichterfelde, a suburban station on the Berlin-Anhalt Railway, to the Military Academy, and this railway has just been successfully opened for regular traffic. It is a single line of 1 metre gauge, a little over  $1\frac{1}{2}$  English miles long. The permanent way has been constructed in exactly the same way as that of railways; wooden sleepers and steel rails are employed, the rails being connected, in addition to the usual fish plates, by short straps of iron, bent in the shape of a bridge, so as to admit the adjustment of the rails to different temperatures, and to reduce at the same time the electrical resistance. As the currents are low tension currents, it was not necessary to provide further insulation, and no difficulty is experienced in using one rail as the positive, and the other as the negative conductor.

About a third of a mile from the Lichterfelde station the primary machine, with its steam-engine, is erected in the engine-house of the water-works, and the current is conveyed from there to the rails by underground cables. The car is exactly similar to an ordinary tram-car, and is constructed to hold 20 persons besides the guard. It is symmetrical, and can move backward and forward, each end being provided with a starting lever for the guard, a brake handle, and a signal-bell. The dynamo machine is placed underneath the car, and transmits its movement to the wheels by means of spiral steel springs. The tires of the wheels are insulated from their axles, and are in electrical connection with brass rings, fastened on the axles, but insulated from them. Contact brushes press against these brass rings, and from them the current is conducted to the dynamo machine, and sets it in motion.

The authorities were, for some time, doubtful how to class this novel railway, and after long deliberation they have decided to rank it as a one-horse tram-car. In consequence of this decision, the average speed on the railway must not exceed 9.3 English miles (15 kilometres) per hour, and the greatest speed at any moment must not exceed 12.4 English miles (20 kilometres) per hour. The time for traversing the whole distance is, therefore, not to be less than ten minutes, although the car could make the journey in about half the time with perfect safety.

If the railway continues to work in a satisfactory manner it is to be extended, and there is no doubt that the success of the railway at Lichterfelde will greatly assist in the further introduction of electrical railways, either on the level of the streets, or elevated, like the steam railways of New York. Over any other system, worked by steam or by compressed air, the electrical has the advantage that no heavy machinery has to be carried about to set the train in motion. The

carriages can, therefore, be built in a lighter manner, thus reducing the power necessary to move them, and permitting all bridges and other superstructures to be built more cheaply than usual. Several carriages, each with a dynamo machine, can be joined to one train, and by this distribution of the motive power much steeper inclines can be overcome than when the same train is drawn by a single locomotive.

In addition to the ordinary brakes, means can be provided to short circuit the machines on the carriages, and to cause them in this way to act as very powerful brakes. The use of large stationary engines reduces the amount of fuel necessary to develop a certain power on the travelling carriage, and if waterfalls can be utilised, the cost of working these railways will be further diminished. It seems, therefore, probable that such railways can be usefully and economically constructed to facilitate the traffic in crowded streets, or in situations where local circumstances favour their application.

From all that has been done during the last few years, it is quite evident that the art of transmitting power by electricity has advanced rapidly, and that its practical application is continually gaining ground. This, however, should not be regarded as a sign that the electric transmission will supersede every other system of transmitting power to a distance, but rather that there is a sphere for it, where it meets existing demands better than our present means; and it should, therefore, not be treated as an enemy of existing systems, but as a supplement to them, by the aid of which problems can be solved, that could not otherwise be attempted.

#### DISCUSSION.

The Chairman said the subject brought before them that evening was one which, though of the highest importance, had been presented in a modest unassuming manner, but there was in the paper matter for very deep consideration. The great utility of some means of transmitting power to a distance had long been recognised, and must be appreciated by all who thought on the subject. The same argument was frequently made use of which had been advanced to-night, that if power could be laid on to houses in small quantities, it might turn the course of industry from the system of large factories to a system in which each workman might work in his own dwelling; but he was not at all prepared to say that such a change, except in special cases, was desirable. The probability was that the workman would have bad ventilation, that he would not attend to his duties so well as he would in a large factory, and that all the economies arising from a well-organised establishment and the sub-division of processes would be done away with, the only advantage being the somewhat sentimental one, that the man worked in his own house. However, this was rather a question for the political economist than for an engineer. Attempts at transmitting power from a distance had been made for many years. He was apprenticed to an engineer (John Hague) who was the very earliest to make the attempt on a large scale. His mode was the exhaustion of air by pumps worked by water-wheels or other suitable prime movers, the exhausted mains being connected to engines in the nature of a steam-engine, and the pressure which the atmosphere exerted on the piston caused it to work. In that way power was conveyed very well indeed—considering the time at which it was done—and very usefully. Notably, it was conveyed to underground engines in coal mines, where it

provided a motor free from the objections of engines in such positions; it was also used to convert a steam-engine into gunpowder manufacturing, to obviate the necessity of fires within the mine. Since then they had had the transmission of power by compressed air, and also by water under pressure, perfected by Sir William Armstrong, by multipliers and various hydraulic engines. He quite agreed with Mr. Alexander Siemens, that the advantages in the electric mode of transmission last two, lay in the fact that with them the friction and leakage could not be accurately calculated because the loss by friction was easily made good, that by leakage was dependent on the care with which the work was carried out, and it ought to be, in fact, extremely small. Then again, there was the transmission of power by means of endless ropes, there was a magnificent example at Basle where the water of the Rhine was made to drive large turbines which drove endless ropes; it carried about three-quarters of a mile along the river, and drove shafting under the mills from which the power was laid on to various mills, and he did not know a more interesting sight than the power of the Rhine thus utilised. Even now we had before us a means of transmitting power by electricity, and no doubt if metal conductor as was on the table could be used for the large exhausted main of John Hague, smaller mains carrying compressed air, or smaller ones carrying water under pressure, the rope running over guide pulleys, it would be gained. Mr. Alexander Siemens said that this mode would be economical even only 45 per. cent. of the power developed by a steam-engine was available at the spot where it was utilised, and did so, on account of economy in working one large central engine rather than a number of small ones, and quite agreed with him, as also in the statement that 2½ lbs. of coal per h.p. was a liberal allowance for a large condensing engine, and that at least used in small non-condensing engines. He pointed out that where water-power was available, it might be utilised in a manner which it was not at present, as, instead of factories having to be placed in inaccessible, out of the way places, the dynamo could be placed there, and connected by water where the manufactures could be carried out with comfort, and where transport was easy. He had the good fortune to see the arrangement at Craigside, where Sir William Armstrong, at Craigside, had a fall of water which drove the machine, the mill led to the house nearly three-quarters of a mile, during the day the force was employed to drive a bench, and at night for illuminating the house. He had not been there since the Swan lights had been introduced; but Sir William Armstrong wrote to him of months ago, saying that the lighting had improved since he saw it. Sir William said the light was perfect, so much resembling daylight the time of writing, he had even been obliged to get up and draw the curtains, because there was a outside trying to commit suicide by coming in through the window. It appeared that the authorities did not know how to classify this new method of lighting, they put it down as a one-horse transmission, and a curious classification he heard of when he visited the celebrated cavern near Aix-la-Petite, where it was lit by candles, and the landlord of the hotel complained that the electric light had been introduced; but Sir William Armstrong wrote to the Prefect objecting, citing a resolution which had been passed by the authorities, that neither gas, nor electricity, nor any other smoke-producing illumination should be employed. With another mode of using electric force, which he touched upon in the paper, he might say 6

ing a most agreeable perfume coming the table before him, which Dr. Siemens the sun, aided by electricity; and he it would prove as good as other fruits from the same source. In this paper they go out of a subject, the importance of difficult to exaggerate. If, by means of it could practically convey power to a great extent, it would be required in anything like proportion of the power originally was perfectly certain that they had as of utilising the forces of nature, was wasted. All round England they had ed and flowed with varying range, but range would be about 15 feet; and if they of water mills, utilise that enormous transmit it electrically to centres of must economise the coal now employed of motive power, and reserve it for those rich, up to the present time, it would was needed, viz., for metallurgical and purposes. At the same time he by no of hearing that it was no longer even for these operations, for it was appear that electricity was able to do ay of melting refractory materials, rto been done by the expenditure of fuel. the paper was so large and important, it would not be too much to ask the Society to devote next Wednesday tinnance of the discussion.

ton said the first point which occurred ing the paper, was in connection with the ich Mr. Siemens arrived at the result cy of electrical transmission ought to um when the velocity of the motor was the generator; but who went on to say ed to be something wrong in this theo- n, because it was not borne out by experi- planation given was the Foucault currents p by induction in the iron. He ventured as another explanation altogether which or the formula not according with ex- ts, and indeed he should not have pre- formula would agree with the results. at the experiments to which they re- de with dynamo machines, in which erated by the machine was used to magnets. Now, supposing they had ctric machines, one driven by a steam- ducing a current, and the other pro- y means of that current, and imagine it exactly the same speed, what would

There would be no current whatever ire joining them; because, if running ped, the electro motive force of the be equal and opposite to that of the motor. as even little current passing between es, it was impossible for the second ive power at all, since there could be on of the field magnets. And yet for evolve rapidly work must be spent in e no useful work were given out; hence e use of dynamo machines which caused result to differ from the practical. The ought to be used were either dynamo- es with separate exciters, or else magneto- es. For the transmission of power effi- omically it was absolutely necessary that ion of the field magnets should not be e current passing through the wires join- nes. But when such an arrangement as as carried out, there would be little differ- theoretical and practical result. It would e economy of the transmission increased of the motor more and more approached

that of the generator; and when both velocities were extremely high, and nearly equal, the efficiency would approach very nearly to 1. There were various considerations which would bear this out. If you made experiments, as his students had done, with magneto-electric machines as motors, measuring the electric energy put into the magneto-electric machine, and at the same time measuring the amount of work given out by it, you did not find that there was a maximum point after which the efficiency diminished. All the experiments he had seen showed that the efficiency increased with the speed; and he had actually obtained with a very high speed an efficiency of 92 per cent. He thought, on the whole, the conclusions Mr. Siemens had arrived at tended to show what Professor Perry and himself had advanced several times, that they ought to use either magneto-electric machines or dynamo machines, with separate exciters; and, to a certain extent, this conclusion was borne out by practical experience, because he learned that in electric lighting, which was but one mode of transmitting power, it was becoming the practice to use separate exciters for the dynamo machines; and that was the method adopted by Dr. Siemens in the City. As the Chairman had pointed out, the great advantage of electricity as a means of transmitting power was not that the friction and leakage inseparable from other methods could not be calculated; but experiments seemed to show that electricity had no mass; that there was no inertia in it; and there was no waste of power in making it go round a corner, as there was with water or any kind of material fluid. In many respects, of course, the flow of electricity through a wire was like the flow of water through a pipe; the quantity of current was constant, and the electricity lost potential, just as water lost head; but there was this great difference between the two, when you had to make water go round a bend you lost a great deal of power, and the form of the bend made a considerable difference. If you had two or more bends in a pipe, in opposite directions, you lost more power than if there were a continuous curve in the same direction; but this was not so with an electric conductor, since bends made absolutely no difference in the electric resistance of a wire. The Chairman had alluded to the great advantage which would result from an enormous quantity of waste power being utilised, and with that he concurred, not so much with regard to the tide, the utilisation of which he feared lay in the dim future, in consequence of the great expense of storing the water when the tide rose, but rather with regard to the water-power of streams. It was quite lamentable to walk about the neighbourhood of Sheffield and see the number of old grindstones which formerly were worked by water-power, now lying idle, the grinders having all gone into Sheffield, where they used grindstones worked by steam-power, which cost them more; but they saved, on the whole, on account of the expense of transportation. If those streams could be used to work magneto-electric machines, from which the power could be conveyed into the town, and there utilised, it would be an immense advantage. There was another point about electric railways which might not have struck some of those present. At present locomotives weighed from 40 to 60 tons, necessitating very substantial and expensive bridges and permanent way, and it was impossible to make them much lighter, or they would not have sufficient adhesion on the rails to pull a train; you could not much diminish the weight so long as you drove a train by one or two pair of driving wheels. But if you drove the train by nearly all the pairs of wheels, as could easily be done electrically, it might be made comparatively light, and there would be no loss by slip. The great value of the paper lay in its technical character; it was a laudable example of the application of principles of science to practice, which characterised all the work of the Messrs. Siemens; and if he had ventured to differ a little

from some small part of the theoretical considerations advanced, he would conclude by assuring the meeting that no one more highly appreciated its practical bearing.

Mr. J. N. Shoolbred said he had made some experiments on the transmission of power, and was much struck by the remarks of Professor Ayrton on the amount of useful power the formulae disclosed, and also as to the nature of the machines which, in his opinion, would have to be employed. He agreed with him as to the errors, which had probably arisen from the use of two dynamo machines, one as the generator and the other as the motor. He had himself long seen reason to doubt the ordinary statement that there must be a loss of 50 per cent. in the second machine, and he hoped, by some means or other, they would be able to discover the proper formulae. With regard to the two classes of machines, spoken of by Professor Ayrton as the best form of primary machines, either magneto machines or dynamo machines with separate exciters, he thought—especially where the same machines were used for lighting and for transmitting power in the daytime—that dynamo machines would be chiefly employed; but they would generally fall under the condition of having one common exciter, and, consequently, according to Professor Ayrton, about 80 per cent. of the original duty given off might be recovered.

Professor Ayrton wished to explain that the figures he had used, and which were quoted in the paper, did not mean that if you gave a certain amount of power to the dynamo-electric machine you could get out 90 per cent. of that in the electric light produced by that machine; it only meant that 90 per cent. of the power given to the machine was reproduced as electric energy. Some of that energy was employed in producing light, but a large portion—often nearly half, or more—was employed in heating the wires or the magnets.

Dr. C. W. Siemens, F.R.S., said he would only make a few remarks that evening, and speak more at length when the discussion was resumed next week. Professor Ayrton had remarked that the dynamo machine would be superseded by the magneto machine, or by a dynamo machine with a separate exciter, and he confessed that he went a long way with him in his argument; indeed, last year he communicated a paper to the Royal Society in which he showed certain defects in the dynamo machine, and suggested certain remedies. The dynamo laboured under this defect, that, with an increase of work, the power to overcome the resistance diminished. The current produced by the rotation of the coils in the magnetic field had to excite the coils of the magnet itself, and the current then passed on to the second machine or to the light, to the place where the work was to be performed. Now if that work should present increased resistance, the machine which had to overcome it should increase in energy, whereas the greater resistance caused a weakening of the current and a falling off in the power of the magnets by which the current was produced, thus causing those fluctuations which were so troublesome in electric lamps, but which, by different arrangements, had been almost overcome, and would be entirely overcome by the aid of further experience. It was quite true that in the City they were working with dynamo machines having separate exciters, but the dynamo machine could be so arranged that a portion only of the current was set aside to excite its own magnet, and if that arrangement were properly applied, he believed all the advantages of a separate exciter could be secured with a single machine. The subject especially before them, however, was the application of electricity to the propulsion of railways and the transmission of power, of which the propulsion of carriages was only one branch. Several other methods by which propulsion could be effected might be mentioned. Only a few days ago he had been in Paris, and had arranged for the

construction of a short line of comparatively broad gauge, which was to be carried out by the omnibus company of Paris, in connection with the Decennial Exhibition. An ordinary tram-car would be run from the Place de la Concorde to the Exhibition, the rails laid in the usual manner, having a suspended conductor along the side of the railway. The omnibus would have a little carriage passing along it, and would transmit the electric current from the suspended wire to the machine, and back through the rails themselves. That arrangement, which was devised by Dr. Wenckebach, made them independent of partial insulation of the rails upon which the carriage ran, and also independent of the partial insulation of the wheels of one axle from the other, leaving the rolling stock very much the same as at present, transferring the current to a separate conductor, something analogous to a single wire telegraph upon which the contact roller ran and conveyed the current to the machine. Another arrangement, in which an ordinary omnibus might be run upon the street would be to have a suspender thrown at intervals from one side of the street to the other, and two wires hanging from these suspenders, allowing contact-rollers to run on these two wires, the current could be conveyed to the tram-car and back again to the dynamo machine at the station, without the necessity of running upon rails at all. He merely mentioned this to show that the question was not one which must be carried out in any particular way only, but was capable of very great modification and extension according to circumstances. The paper referred to certain applications which he had made of electricity, near Tunbridge-wells, to horticulture, and on the table was a melon which had been produced by the aid of the electric light. He hoped the Chairman would take it home, and report upon it next week.

The Chairman said if it turned out as good as electrically-grown fruit which he had tasted, his would be far from a disagreeable one. He then declared the meeting adjourned until Wednesday next.

## MISCELLANEOUS.

### BRUSSELS INTERNATIONAL EXHIBITION

This Exhibition, due to private initiative, was at first with the object of receiving foreign products and inventions which were not admissible at the national exhibition in the Champ des Mars. The Palais du Midi, which was originally intended for a market, was completed with a special view to its present destination, and formally opened by the King and Queen of the Belgians, accompanied by Sir Savile Lumley, the British Minister, on 1st June, 1880. It was intended to be permanent, but the great falling off in attendance during the winter months has induced the committee of management to terminate the present exhibition with its first year's existence, and on 1st June next to open the first series of annual exhibitions, from June to October, with special classes, varying each year.

The classes fixed upon for the present year are: 1. Carpets of all kinds, including felt, mats, and rubber; 2. Tapestry and other fabrics connected with furniture, including American cloth; 3. Upholstery, curtains and hangings; 4. Works of the decorative arts, including plaster of Paris, carton-pierre and papier-mâché; 5. Shawls, 6. Lace and tulle; 7. Embroidery and trimmings; 8. Dress and its accessories; 9. Ceramic ware, both porcelain and pottery; 10. Glass and crystal ware; 11. Window and stained glass; 12. Art bronzes, zinc, and iron; 13. Goldsmiths' lighting and heating appliances; 14. Goldsmiths' and jewellers' work.

lery; 15. Arms and outlery, including surgical  
ts; 16. Musical instruments; 17. Cabinet  
. Art joinery and parquetry; 19. Decorative  
and marble work; 20. Travelling and miscel-  
objects: 21. Artificial flowers; 22. Usual  
of the arts of drawing and wood-cutting,  
mechanical drawings, lithography, chromo-  
my, engraving, photography and photography;  
paper, including imitation leathers, writing  
office requisites; 24. Clocks, watches, chro-  
pedometers, clepsydræ and sand-glasses;  
means of typography, autographic proofs, new  
editions, periodical publications, atlases, art  
printing ink and accessories; and 26. The  
machines employed in the above classes.  
Commissioner is M. B. F. Pasquier, engineer; and  
Administrative Council comprise M. M. Felix Tasson,  
Janssens, H. Weber, Alfred Brasseur, and  
Vascher; the engineer is M. Th. Devadder,  
engineer of the Belgian State Railways, who  
the buildings at the Exposition d'Hygiène in  
their information may be obtained from, and  
should be addressed to, the General Manager,  
de Bavay, Palais du Midi, Brussels.  
Objects in the Exhibition, now about to close,  
tures of industrial, humanitarian, or sanitary

esting demonstration of the saving of sub-  
ch have hitherto been allowed to pass away  
afforded by a collection shown by the Société  
es Produits du Flénu, Belgium, of the sub-  
stained in their process of coke making.  
Some excellent specimens of tar, ammoniacal  
sme, benzine, various light oils, heavy oils  
ng timber, naphthaline, anthracène, pitch,  
onia, &c.

bition contains some new applications of iron,  
ght and cast. The Compagnie des Forges  
ow some hexagonal pavings, which they make  
out sheet iron into moulds, giving them a  
d at the same time a deep flange, so as to  
to keep their place when imbedded in sand.  
l Gilquart, of Labuissière, shows a similar  
for roofing purposes. He presses out the  
nto the form of roofing tiles for overlapping  
; and some of them are provided with a  
of glass. A new industry has lately sprung  
um, that of enamelled wrought-iron ware for  
; crockery; it has the disadvantage, however,  
causes the enamel to fly off at the spot where  
has struck. The Société des Fondries et  
show a case containing representative  
of the new ware, which is ornamented  
erns like earthenware, from which it  
ily be distinguished by sight. M. Per-  
Geneva, exhibits some paving-blocks con-  
hollow cast-iron shell filled with concrete,  
me tramway chairs made in the same manner.  
e latter have been taken up after service, and  
to show the fracture. The same inventor  
his system of insulating underground tele-  
ms. He makes small cylinders of enamelled  
re, pierced with holes in the direction of their  
he wires pass through these holes, and the  
are protected and kept in place by lengths of  
ubes, divided longitudinally and horizontally  
laying.

method of reproducing industrial drawings,  
aid to be greatly superior to the prussiate of  
ues" that have lately become common on the  
is exhibited by M. Ad. Joltran, of Paris.  
are produced by the aid of the sun acting on  
mmo-ferrique," and the lines appear of an  
on a white ground, with all the clearness of  
ils.

one-tenth real size, is shown of some tem-  
rds which have been put up for cases of in-

fectious diseases at the Hôtel Dieu, Châtelet, designed  
by Dr. Gallez. They are isolated by a system of passage,  
the two sides of which are closed by framework, but can  
be left open, if desired, so as to allow the free access of  
air. The framework is of 1-inch pitch-pine, varnished,  
and made double, so as to enclose spent tan, saturated  
with a solution of sulphate of iron, for preventing any  
danger of infection to other patients. The wards are  
warmed by the ventilating stove of the Société, H. J.  
Piron et Cie, of Hodimont Verviers, which produces an  
active ingress of fresh air, and is so constructed, that  
the warmed air does not come in contact with the  
furnace. Mr. F. V. Mouly, of Brussels, shows his  
"Calorifère atmosphérique et hydrothérapique," which  
permits of simultaneously warming and ventilating an  
inhabited building, a green-house, and a place of public  
réunion, while supplying hot water for the baths and  
lavatories. The heating surface warms the air, com-  
bined with water for hygienic considerations; but the  
flues, uniting in a single chimney, also contribute to  
warm the building and draw off vitiated air, being sur-  
mounted by a special aspirator. Mr. E. G. Banner was  
awarded a gold medal for his ventilators, some new  
forms of which are exhibited; while it was practically  
demonstrated that the wind, blowing with average  
velocity through a one inch-cowl, is capable of draw-  
ing foul air through 72 feet of one-inch india-rubber  
tubing.

M. Systermans contributes a full-sized section of rail-  
way carriage filled with his safety appliances for the  
protection of the guards when passing from carriage to  
carriage. A belt, passed round the guard's waist, is  
attached by a swivelling spring catch to a ferule, which  
slides along a continuous handrail, attached to the off-  
side of the carriage. The ferule is so arranged as to  
clear the fastenings of the hand-rails, which are con-  
nected from carriage to carriage by a jointed rod, so as  
to afford uninterrupted communication. Mr. W. Bren-  
ton, of St. Germans, received a silver medal for his  
safety door and window fastenings; he also shows some  
traction springs, made by Messrs. Fairholme and Co.,  
of London, for facilitating the start of tram-cars, rail-  
way trucks, and other heavy vehicles drawn by horses.

The engine driving the machinery in motion is sup-  
plied with steam by a system of safety boiler, which was  
designed by M. De Nayer, papermaker, of Willebroek,  
for his own use, but is now becoming generally used in  
Belgium. The boiler is composed of tubes, in which the  
steam is generated, connected by wrought or malleable  
iron receivers. Two tubes form an "element;" and these  
are in turn connected by short tubes with conical joints,  
perfectly tight, without any cement or packing. The  
small diameter of the tubes, and the great strength of  
the materials employed, render this boiler practically  
inexplosive; but if, through any unforeseen defect in the  
metal, a tube should give way, the explosion would be  
confined to that tube, and produce none of those  
disastrous effects attending the bursting of ordinary  
shell boilers. The evaporation is from eight to nine  
pounds of water per pound of small coal. M. J. Barbe,  
of Brussels, exhibits his additional safety valve, which  
he applies to the under-side of ordinary boilers for pre-  
venting explosions. Messrs. A. H. Bateman and Co.,  
of East Greenwich, who were awarded a bronze medal,  
show, among other objects, their safety boiler fittings,  
consisting of—(1.) A new safety valve, in which three  
spiral springs are substituted for a single large one;  
a lever is added for raising the valve off its seat from  
time to time, to make sure that it has not set fast, and  
when once adjusted to the required pressure the engine-  
man cannot alter it, although the working parts are  
perfectly visible. (2.) A new water-gauge, in which,  
on the glass breaking, all escape from the boiler is at  
once prevented, thus obviating the danger of scalding  
so common on locomotives. (3.) An improved steam  
sentinel, which gives warning, by whistle, of an excess  
of pressure, having a lever added to prevent the valve

from remaining fast on its seat. (4.) An improved conical form of fusible plug, for preventing explosions, owing to deficiency of water.

Life-saving on the water was represented by Messrs. C. W. Meiter, of London, with Colonel de la Sala's folding boats and rafts; and M. Verhaaren Rowet showed his safety air-tight cans for holding volatile and inflammable substances.

### FAURE'S SECONDARY BATTERY.

Considerable interest has lately been aroused by the announcement that a Paris electrician has discovered a new method of storing electricity. The invention is really a new secondary battery, or, rather, an improvement on the well-known secondary battery of M. Planté. A secondary battery, it is hardly needful to say, is one which is charged by the action of a battery, or machine, and then gives out this charge as required.

In the Planté battery the electrodes are of lead, and they are immersed in acidulated water.

In M. Faure's battery the two lead plates of the couple are each covered with minium (red lead) or another insoluble oxide of lead, then enclosed in felt, kept in place by lead rivets. These two electrodes are then put side by side in a vessel of acidulated water. If they are very long, they are rolled up like those of M. Planté. Thus constructed, the couple is charged by causing an electric current to traverse it, when the red lead is reduced to the state of peroxide on the positive electrode and lead upon the negative electrode. When the whole mass has been thus electrolysed the couple is ready for discharging. On being discharged again, the reduced lead is oxidised, and the peroxide is reduced until the couple becomes inert. It is then ready for a new charge of electricity.

It is stated that a quantity of energy can be stored capable of performing a horse-power of external work during an hour in a Faure battery of 75 kilograms in weight.

A correspondent of the *Times*, "F.L.R.S." has since given an account of a meeting of the Société d'Encouragement pour l'Industrie in Paris, presided over by Mons. J. B. Dumas, at which Mons. Faure's battery was exhibited, and the following somewhat enthusiastic description of a box containing four batteries, which was taken by the writer from Paris to Glasgow:—

On Monday, 9th inst., in Paris, a Faure battery, or *pile secondaire*, was charged with the electric fluid direct from the ordinary Grove battery, and in my presence. In may be more economically done from a Gramme or Siemens machine. The receptacle consisted of four Faure batteries, each about 5 in. diameter and 10 in. high, forming a cylindrical leaden vessel, and containing alternate sheets of metallic lead and minium wrapped in felt and rolled into a spiral, wetted with acidulated water, and the whole placed in a square wooden box, measuring about one cubic foot, and weighing some 75 lb. This was protected by a loose wooden cover, through which the electrodes (in lead) protruded, and were flattened down for convenience of transport. This box of "electric energy" was handed to me by M. Faure, at my request, with the object of submitting it for examination and measurement to our eminent electrician, Sir William Thomson, F.R.S., at the University of Glasgow. I had the box by me all through the journey from Paris on Tuesday night, including a five hours' delay at Calais. I arrived at Charing-cross at 11 a.m. on Wednesday, after running the gauntlet of customs and police authorities, who suspiciously looked askance, and seemed to doubt my statement that my box only held "condensed lightning," and contained no infernal machine or new explosive destined to illustrate some diabolical socialistic tragedy. From time to time on the journey I tested the force of the discharge, and found it to have well maintained its energy. From London to Glasgow

required only another 10 hours, and finally, hours from the time of charging in Paris satisfaction of presenting to Sir William T. Faure's rare offering of a "box of electric and potent, holding by measurement within space of one cubic foot, a power equivalent one million of foot pounds! This wonderful deposited in the laboratory of the Glasgow under the vigilant eye of its director, and mitted to a series of tests and measurement

### TASAR SERICICULTURE IN IN

The following report from Major Coussins forwarded by the Secretary of State for Indication in the *Journal of the Society*:—

Camp Rajur, Taluka Akola, 6th  
SIR,—I have the honour of acknowledging (No. 659) of the 23rd ultimo, with its accom and beg herewith to submit, for the inf Government, my report upon the progress in tasar sericulture during the last year.

2. I must first state that, though I have been in gathering a crop of cocoons of my own have yet gained so much more experience or lodge of the difficulties in the way that I have eventually be able to overcome them without the expense of the cultivation.

3. My failures last monsoon were owing perfect construction of the cages in which I the worms. These were at first entirely made screens of split bamboo, and served the pur ing out rats, mice, birds, squirrels, and being dark, the plants did not thrive well, as were always striving to escape. I then alt struction, made them longer and put netting instead of pieces of screen, and here every well for a time, until some wasps and I managed to get in and puncture the silk the effects of which the majority died, as lived to spin their cocoons. I shall try t this next monsoon with coarse open cotton will, I expect, turn out to be cheaper than

4. The small plantation which I have thriving, and will, eventually, be able to su siderable number of worms, but I have ha plan to a certain extent. I adhere to my or tion of keeping the plants well pruned, letting them grow more than three or fou but in order to make the junctions of the s secure and vermin proof, I must have th banks seven feet wide instead of four. I moved to other ground all the other plants "Lagerstramia Indica" (*Gul Mendhi* or the "Zizyphus Jujuba" (*Bhar* or *Bhort*), the two kinds which thrive best with me, now five hundred feet of the former and th of the latter available for feeding purpo several outtings and seedlings which are co

5. My collection of cleaned, perforated co for the manufacture, now amounts to ab weighing about 60 lbs., and sown up in ba state they will remain without deteriora indefinite period. Of this amount the For ment, working under Mr. Shuttleworth's i contributed this season about 17,000, wh mainder consist of those which I have col other sources, or carried forward from last propose to wait till I have got 1 cwt. before steps towards disposing of this material, a factorer would care to purchase a small amo

6. One of the most promising facts in conn tasar sericulture is the effort which is being Mr. George Baird with the encouragement Mahārāja to establish a plantation at Odey.

st advanced students in Mr. Baird's school ooms by the direction of the Maharaja, and ny house daily for some weeks, watching the he insects, and taking copious notes, which e, bear fruit some day.

it up my usual correspondence with individuals in the scheme, and distributed eggs to them ur, Khāudesh, Coorg, Rangoon, Ceylon, and

ig to changes among the members of the partment. I have not yet been able to get all its settled, but as far as I can tell, I shall nded about Rs. 220 of the 500 placed at my Government last year, of which about Rs. 45 been paid to villagers for cocoons, Rs. 10 on and the remainder on laying out and maintain- lantation, in tending the silkworms, and in cocoons for storage.—I have the honour to  
G. COUSSEMAKER, Major.

### BRITISH ASSOCIATION.

lowing arrangements have been made for the meeting of the British Association, to be held —The first general meeting will be held on y, August 31, at 8 p.m. precisely, when A. y, F.R.S., V.P.G.S., will resign the chair, ohn Lubbock, Bart., M.P., F.R.S., President- ll assume the presidency, and deliver an On Thursday evening, September 1, at 8 irte; on Friday evening, September 2, at 8.30 icsourse by Professor T. H. Huxley, LL.D., on Monday evening, September 5, at 8.30 scourse by W. Spottiswoode, D.C.L., LL.D., of the Royal Society; on Tuesday evening, 6, at 8 p.m., a *soirée*; on Wednesday, 7, the concluding general meeting will be 30 p.m. No report, paper, or abstract can be the Report of the Association, unless it is efore the conclusion of the meeting. Excursions of interest in the neighbourhood of be made on the afternoon of Saturday, 3, and on Thursday, September 8.

eral officers are—General Secretaries: Capt. alton, C.B., D.C.L., F.R.S.; Philip Lutley h.D., F.R.S. Acting Secretary: George f.A., F.C.S., Harrow; General Treasurer: W. Williamson, F.R.S. Local Secretaries: nas Adams, M.A.; Tempest Anderson, M.D., rk. Local Treasurer: W. W. Wilberforce,

tions are arranged as follows:—

*Mathematical and Physical Sciences.*—President: William Thomson, F.R.S. Secretaries: Prof. ynton; Oliver J. Lodge, D.Sc.; and Donald ; B.A., B.Sc. (Recorder).

*Medical Sciences.*—President: Prof. A. W. m, For. Sec. R.S., V.P.C.S. Secretaries: . Dixon, M.A., and P. Phillips-Bedson, D.Sc. r).

*Geology.*—President: Andrew Crombie Ramsay, F.R.S. Secretaries: W. Topley, F.G.S. r) and W. Whitaker, F.G.S.

*Geology.*—President: Richard Owen, C.B., F.R.S. es: G. W. Bloxam, M.A., F.L.S.; W. L.

W. A. Forbes, F.Z.S.; Professor M'Nab, ohn Priestley; and Howard Saunders, F.L.S.,

*Department of Zoology and Botany.*—Richard l.B., F.R.S. (President), will preside. Secre- professor M'Nab, M.D. (Recorder), and Howard , F.L.S., F.Z.S. *Department of Anthropology.* or W. H. Flower, F.R.S. (Vice-President), ide. Secretaries: G. W. Bloxam, M.A., F.L.S. r), and W. L. Distant. *Department of Anatomy ology.*—Professor J. S. Burdon Sanderson,

F.R.S. (Vice-President), will preside. Secretaries: John Priestley (Recorder), and W. A. Forbes, F.Z.S.

*E. Geography.*—President: Sir J. D. Hooker, K.C.S.I., C.B., F.R.S. Secretaries: H. W. Bates, Assist.-Sec. R.G.S., F.L.S., and E. C. Rye, Librarian R.G.S., F.Z.S. (Recorder).

*F. Economic Sciences and Statistics.*—President: The Right Hon. M. E. Grant Duff, M.P., F.R.S. Secre- taries: Constantine Molloy (Recorder), and J. F. Moss.

*G. Mechanical Science.*—President: Sir W. G. Arme- strong, C.B., F.R.S. Secretaries: A. T. Atchison, M.A. (Recorder), and H. Trueman Wood, B.A.

Tickets for the meeting may be obtained of the Local Secretaries at York, and at the office of the Association, 22, Albemarle-street, London, W.; or on application by letter, from August 17 to August 24, to the General Treasurer, Professor A. W. Williamson, British Association, University College, London, W.C.

### QUEBRACHO WOOD.

Mons. F. Rhem has lately communicated a paper on the "Quebracho Wood" to the *Société Industrielle du Rouen*, from which the following particulars are extracted:—This wood belongs to the family of the *Asclepiades*, and comes from America. Being very hard, and composed of a great quantity of interlaced fibres, the tannin it contains is different from that of chestnut or of oak. Gelatine precipitates this tannin out of a water solution with a flesh colour, while salts of protoxide of iron give an ash-grey precipitate, and the peroxyde salts a dirty greenish colouration. When boiled with weak sulphuric acid, the tannin is not converted into gallic acid. According to a German chemist, quebracho wood contains 18 per cent. of tannic acid. The bark of this wood contains an alkaloid analogous to quinine. Extract of quebracho, now much used in wool dyeing, giving a yellow shade with a tin solution. It gives even shades, resembling those of cutch, if used with bichromate of potash, but its principal use is for obtaining blacks, for which the wool is given first a bottom of the extract, then passed through iron, and dyed with the quebracho; this, in these conditions, can replace cutch. Solutions of quebracho wood, or extract, will only keep limpid if heated to a certain temperature, but get turbid on cooling. Dyeing experiments, with the dry quebracho extract, as manufactured by a French firm, in comparison with cutch, have proved the former of more value, since, with a lower price, it possesses a greater richness of colouring matter. Three series of trials were made: one, by passing the cotton prepared in a quebracho or cachou bath through bichromate of potash; the second, through iron; and, in the third, the patterns were passed through iron and then chromed. In all cases the same results were obtained, showing the advantage of the quebracho over cutch, in spite of a slightly more greyish shade of the colours obtained with the former. The same results have been got by printing mordants on calico, ageing, dunging, and dyeing with quebracho extract or cutch; in all cases the quebracho shades being identical with those of cutch, not only for the tone of colour, but also in regard to fastness.

### GENERAL NOTES.

*Ladies' Sanitary Association.*—At the meeting of this association, held last week, on the occasion of the distribution of prizes by H.R.H. Princess Christian, of Schleswig-Holstein (see *Journal*, p. 552), Sir Henry Cole, in reply to a vote of thanks passed to the Society of Arts for the use of the hall, said it was the business of that Society to do what other people—Government especially—did not do, and to show the Government a better way of doing things. At

present the Society was engaged in a most interesting work. Ladies were doubtless aware that in this country the system of teaching needlework was confined to senior wranglers. Now this Society was trying to induce ladies to conduct a course of instruction in domestic economy, including the teaching of needlework, the making of clothing, cooking, and other arts in which woman shone pre-eminently, but the teaching of which, by accident, had got into the hands of men.

**Suez Canal.**—In the course of 1880, 2,017 ships passed through the canal with a tonnage, according to official reckoning, of 2,860,448, but really amounting to 4,378,964. The number of hands employed in the navigation was 128,453; the number of passengers, 53,517. Of the 2,860,448 tons official reckoning, 2,247,306 were British, 177,771 French, 75,820 Austrian, 124,083 Dutch, 71,039 Italian, 56,245 Spanish, 38,162 German, 29,607 Russian, 7,203 Turkish, and 8,032 Egyptian, while 25,180 tons belonged to other States.

**Total Production of Coffee.**—According to the *Batavian Journal of Agriculture*, the production of coffee by the whole world, in 1855, was 330,152 tons, and, in 1878, no less than 490,843 tons, showing an increase during the 23 years of 160,675 tons. These quantities were yielded by the following countries:—

	1855.	1878.
Brazil .....	163,400 tons.	226,500 tons.
Dutch Indies .....	71,322 "	91,406 "
West Indies .....	29,300 "	41,800 "
British India and Ceylon ..	28,780 "	53,422 "
South Africa .....	22,315 "	35,890 "
Arabia .....	6,176 "	2,779 "
Africa .....	4,000 "	4,000 "
Central America .....	3,500 "	32,500 "
Philippine Islands .....	1,359 "	3,397 "
Oceania .....	— "	150 "
	330,152	490,843

## MEETINGS OF THE SOCIETY.

### ORDINARY MEETINGS.

Wednesday evenings, at eight o'clock:—

MAY 25.—Adjourned Discussion on Mr. ALEXANDER SIEMENS's paper on "The Electrical Railway, and the Transmission of Power by Electricity."

### FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at eight o'clock:—

MAY 31.—"The Principality of Loo Choo." By Consul JOHN A. GUBBINS.

### CANTOR LECTURES.

Monday evenings, at eight o'clock:—

The Fifth Course will be on "Colour Blindness and its Influence upon Various Industries," by R. BRUDENELL CARTER, F.R.C.S. Three Lectures.

#### LECTURE II.—MONDAY, MAY 23.

Mistakes of the colour-blind in daily life. Their methods of endeavouring to counteract the consequences of their defect. Modes of testing for colour blindness. Sources of error in testing. The actual prevalence of the affection in this and other countries, and in different classes of the population.

#### LECTURE III.—MONDAY, MAY 30.

Industries chiefly affected by colour blindness—Engine-drivers, pilots, artists, letter-sorters, drapers, painters, &c., &c. Recent legislation affecting colour blindness in America, and urgent need for it in this country. Conclusion.

### MR SHELFORD BIDWELL'S PAPER.

In consequence of Mr. Bidwell's severe indisposition, he has been unable to prepare his paper on "Telegraphic Photography," announced to be

read before the Applied Chemistry Section on Thursday, May 26th, and has, therefore, been unavoidable postponed.

## INDIAN SECTION.

Sir Arthur Playfere's paper on "Burn the discussion, will be printed in the *Journal*.

## MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 23RD.—SOCIETY OF ARTS, 8 p.m. Adelphi, W.C. 8 p.m. (Cantor Lecture) Brudenell Carter, "Colour Blindness, and its Influence upon Various Industries." (Lecture II.) National Indian Association, 11, Chandos-street, W., 8 p.m. Mr. C. N. Banerjee, "Home Ex Indian Ladies." Royal Geographical Society, University College, London, W., 8 p.m. Annual Meeting. British Architectural Association, 9, Conduit-street, W., 8 p.m. Distribution of Medals and Prizes. 2. Prof. "Some Observations on the Mariette Expedition to Sakkarah, in reference to Discoveries made there." Geologists' Association, University College, London, 8 p.m. to Sheppey.

TUESDAY, MAY 24TH.—Royal Institution, Albemarle-street, W., 8 p.m. Prof. Dewar, "The Non-Metallic Elements." (Lecture V.) Medical and Chirurgical, 53, Berners-street, W., 8 p.m. Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. John I. Paper, "Torpedo Boats and Light Yacht Steam Navigation." 2. Mr. R. Brunton, "The Production of Paraffin Oil."

Anthropological Institute, 4, St. Martin's-street, W., 8 p.m. Dr. Allen Thomson, "Some Notes from the Andaman Islands." 2. Mr. E. H. Arts of the Andamanese and Nicobarese. Walhouse, "Some Vestiges of Girl Sacrifice and Contracted Intermarriage in India and the Royal Horticultural, South Kensington, S.W.

WEDNESDAY, MAY 25TH.—SOCIETY OF ARTS, Adelphi, W.C., 8 p.m. Adjourned Discussion Alexander Siemens's paper, "The Electric and the Transmission of Power by Electric Geological, Burlington-house, W., 8 p.m. Hicks, with an appendix by Mr. E. Ethel Discovery of some Remains of Plants at the Denbighshire Grits, near Corwen, N. 2. Mr. Edgar Willett, "Notes on a Mass from the Purbeck Beds at Swanage, Dorset." H. G. Seeley, "The Reptile Fauna of the nation."

Royal Society of Literature, 4, St. Martin's-street, W., 8 p.m. Mr. C. Pfundner, "The Popular Old Japan."

Telegraph Engineers and Electricians, 4, Th Westminster, S.W., 8 p.m. Mr. P. V. Construction and Working of a Military graph, based upon Experience gained during campaigns in Afghanistan in 1878-79-80. National Education Union, Westminster I S.W., 8 p.m. Annual Meeting. Ascham Society, 18, Baker-street, W. Royal Botanic, Inner-circle, Regent's-park, 1 Summer Exhibition.

THURSDAY, MAY 26TH.—Linnean, Burlington-house, Anniversary Meeting and President's Address Royal Institution, Albemarle-street, W., 8 p.m. Tyndall, "Paramagnetism and Diamagnetism." Inventors' Institute, 4, St. Martin's-place, Annual Meeting.

FRIDAY, MAY 27TH.—Royal United Service Institute, 3 p.m. Major-General D. J. Newall Colonisation as a Reserve for India." Royal Institution, Albemarle-street, W., 8 p.m. Meeting. 9 p.m. Prof. H. R. Roscoe, "A duction of Indigo." Quekett Microscopical Club, University College, 8 p.m.

Clinical, 53, Berners-street, W., 8 p.m. National Health Society, 23, Hertford-street, (Drawing-room Lectures.) Mr. Ernest H. Progress in Health Knowledge."

SATURDAY, MAY 28TH.—Physical, Science Schools, Tottenham, S.W., 3 p.m. Royal Institution, Albemarle-street, W., 3 p.m. E. Turner, "Russian Literature." (Lecture postponed.)

## OF THE SOCIETY OF ARTS.

No. 1,488. Vol. XXIX.

FRIDAY, MAY 27, 1881.

For the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## NOTICES.

## CONVERSAZIONE.

by's *Conversazione* is fixed to take place at Kensington Museum (by permission of the Committee of Council) on Thursday, the 2nd June.

A Chamber Concert will be given by the String Royal Engineers, in the North Court. Mr. J. H. Grain will give Three short recitals in the Lecture Theatre. Madame de Winter will give a Pianoforte Recital in the Lecture Theatre.

Exhibitions containing the Raphael Cartoons, the Banks Collection, the Wm. Smith Collection of Colour Drawings, the Dyce and Sturt Collection of Paintings lent to the Society of the late Rev. Pryce Owen, and the "Bequest of the late Sir John Bequest," will be open.

The Galleries and Corridors of the Ground Floors will be open.

A Reception will be held in the Architectural Library on Friday, the 2nd June, at 7.30. Mr. F. J. BRAMWELL, F.R.S., Chairman, and Members of the Council.

Invitations of invitation have been issued to

## CANTOR LECTURES.

The first lecture of the fifth Course, on "Colour Blindness and its Influence upon Various Trades," was delivered by R. BRUDENELL, F.R.C.S., on Monday, 23rd inst. The lecturer related some of the mistakes of the blind in daily life, and their methods of avoiding to counteract the consequences of blindness. He described the modes of testing for colour blindness, and the sources of error in the tests which have been adopted. Prof. Brudenell's test, by means of skeins of coloured threads, as explained and illustrated, and the results included with statistics of the actual cases of colour blindness in this and other

countries, and in different classes of the population.

The lectures will be printed in the *Journal* during the autumn recess.

## ART FURNITURE EXHIBITION.

The Exhibition of Works of Art Applied to Furniture, in connection with the Exhibition of Fine Arts at the Royal Albert Hall, was opened on Saturday, 21st inst. A non-transferable season ticket will be sent to any member of the Society on application to the Secretary.

## PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Dr. Hullah, the Society's Examiner, at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 4th July, 1881.

## HONOURS.

The Examination in Honours will consist of three sections, viz., a paper to be worked, an examination similar in form to the practical examination for a First and Second-class, and a *viva-voce* examination.

## FIRST AND SECOND-CLASS.

## Vocal.

Candidates for a First or Second-class Certificate in Vocal Music will be required—

[1.] To sing a solo, or to take part with another candidate in a duet, already studied.

[2.] A key-note being sounded and named by the Examiner, the candidate to name sounds or intervals, or successions of sounds or intervals, played or sung by the Examiner.

[3.] To sing or sol-fa at sight passages selected generally from classical music.

## Instrumental.

Candidates for a First or Second-class Certificate in Instrumental Music will be required—

[1.] To play a short piece, or a portion of a larger work, already studied.

[2.] A key-note being sounded and named by the Examiner, the candidate to name sounds or intervals, played by the Examiner.

[3.] To play a piece or portion of a piece at sight.

The examination of each candidate will be private; no one but the Examiner and the accompanist being present, unless it be a member of the Society of Arts' Committee.

No list of Candidates will be published.

Full particulars can be obtained on application to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

## INDIAN SECTION.

Friday, May 13th, 1881; Sir RUTHERFORD ALCOCK, K.C.B., in the chair.

The paper read was—

## BRITISH BURMA.

By General Sir Arthur Phayre, G.C.M.G., K.C.S.I., C.B.

The province of British Burma, by the rapid progress that it has made in material prosperity during the last twenty years, has attracted the attention of all who are interested in the empire of India. In submitting to this Society a brief account of the present condition of that country, it is necessary to state that statistics of trade and revenue are not available for a later period than 1879-80, but the population by the census of this year has just been received, and that for the purpose of illustration of the comparative progress of the province, it is not proposed to do more than briefly refer to some of the statistics for a few years preceding that above mentioned.

It is scarcely necessary to remind you that the country called Burma, that which is inhabited mainly by people of the Burmese race, and which is as distinctively the country of the Irawadi and its tributaries as Egypt is the gift of the Nile, is divided politically into two parts: British Burma, and Independent Burma. It is proposed on the present occasion to deal principally with the former, and to refer only incidentally to the latter.

British Burma was formed, to speak generally, from the union of three maritime provinces, two of which, Arakan and Tenasserim, were annexed to the British Indian Empire in 1826, and one, Pegu, which became British territory in 1852. The province has a direct sea coast line extending about nine hundred miles along the eastern shore of the bay of Bengal. Though for such an extent the number of ports is limited, yet the outlets of the great rivers give at Akyab, Bassein, Rangoon, and Moulmein, admirable positions for trade with other countries. The province has an area of about 94,000 square miles, being a little larger than Great Britain.

The Burmese people who, including the Talains or Peguans, form about five-sixths of the population of British Burma, are classed by ethnologists as Mongoloids. The numerous hill tribes, Karens, Khyengs, Kamis, and others, belong to the same family. The Burmese, by their physiognomy as well as by their language, show that they belong to the same family as the Bhote, or people of Tibet. The connection from the one to the other, though their countries are so far apart, may be traced by similarity in the physical form, and speech of tribes dwelling on the south-eastern border of the great plateau of Tibet, and bordering the way along the courses of rivers to the country of the middle Irawadi. The Burmese language may be roughly described as monosyllabic, though this classification can only be applied to it with considerable modification. The

Talaing people, who chiefly inhabit the the Irawadi, may, no doubt, be trace same original seat as the Burmese; b ancestors appear to have left it at a mu period than the forefathers of the latter language, which now differs materially from the Burmese, has become nearly extinct, is, perhaps, a larger Talaing-speaking Siam than in Pegu. The total popul British Burma, by the census of this year, to 3,704,253 souls. In order to show t increase in population which has taken may now be stated that, in 1855-6, the amounted to 1,252,555 souls. Probably t may then have been under-stated from returns; but even supposing that the reached to so much as a quarter of a millio one-fourth of the whole, the fact will rem in a quarter of a century, the population has trebled. This, no doubt, has resulted from immigration from Upper Burma, l people are also increasing from natural caus sequent on freedom for their industry, the of war, and, it is believed, generally in sanitary condition from better food and cl

The amount of imperial revenue—the including what is collected by municipal raised from this population amounted, in in round numbers to £2,100,000. That greater proportional amount than is paid other province under the Government of I may, at the same time, be noted that the collected in 1855-56 was, in round £531,792. While, therefore, in twenty-l the population has nearly trebled, the rev nearly quadrupled. This great increas assured, has resulted from general inc prosperity, and not from excessive tax may add that the only item on which I w to see a reduction in the annual revenue arising from the consumption of opiu quantity consumed might be very much by Governmental action with great adva the community, and I learn within the last that measures have been adopted for that

In considering the question of progre prosperity of British Burma, nothing instructive than the continued regular in the area of cultivated land. By most important agricultural product It may almost be considered the or cultural product of British Burma, som it exceed in quantity all others. This from the soil and climate being very su that cereal, and to the people thorough standing the method of cultivation required the native Government, rice was not all be exported by sea, from the notion that s sary an article of food should be kept in the as a reserve in case of famine. Consequ more was produced than was required consumption. After the country became and sale of produce was unrestricted, the at once extended their cultivation. There be seen in the following figures. In 1855 total area of cultivated land paying re Government was 1,076,374 acres. In 1879 area was 3,364,726 acres. The value of ported by sea was, in 1855-6, £1,482,476 1879-80, £5,274,311.

Burma is owned by small proprietors. Property in the soil is independent of any power, and is so laid down in the scriptures. The average area of each village, which rice is raised, is not more than 100 acres. That is the area available for cultivation. Grazing land is that which is left to each village, and is common to the village thereof. All owners exercise the right of sale, gift, and mortgage, though sale is very seldom made. There appears to be no objection to it which may almost be called a right of the rights of heirs, which is inherited, and when land is sold by deed, the seller has expressed that the object of the sale is to build a pagoda or other religious edifice. This is supposed to justify the sale, and land is occasionally let from year to year for agricultural engagement, the tenant agreeing to pay 10 per cent. of the produce.

The development of commerce in British Burma has increased with the increase of population and the export of rice has already been in connection with the extension of cultivation.

The export of rice has already been in connection with the extension of cultivation. The trade of the province may be classed as (1) that carried on by sea with foreign countries, British India; and (2) that carried on by land, or by inland caravan traffic with Burma, China, and Siam.

The increase in the sea-borne trade will be a comparison of figures for 1879-80, and for 1871-72. For both years all imports and exports of goods on account of the Government are excluded.

#### 1871-72.—Imports and Exports.

merchandise .....	£6,938,202
.....	1,311,366
Total.....	8,249,558

#### 1879-80.—Imports and Exports.

merchandise .....	£12,348,373
.....	3,206,939
Total.....	15,555,312

It is not necessary to do more than mention the principal articles. The two of most importance to the United Kingdom are the cotton and the woollen goods, the cotton twist and yarn of manufacture. The value of those goods in the year 1871-72, amounted to £88,372. In the year 1879-80, the value of the former amounted to £153, and woollen manufactures to £177.

When I say these were of British origin, it should be noted that, strictly speaking, 7 per cent. of the goods were shipped from the United Kingdom. Considering the smallness of British Burma small in comparison with most provinces in British India, this is a large proportional amount of annual production. Of the quantity of such goods supplied to people in the interior, in the British frontier, I will speak here to notice the inland trade.

The exports from British Burma by sea consist of rice, the value of which has already been given for one year. The next article in importance is teak timber, which is probably the most valuable wood known for ship-building and

industrial purposes. There has been a considerable falling off in the export of teak timber within the last five years. In 1875-76, the value exported amounted to £432,889, and in 1879-80, to only £273,967.

Teak timber exported is grown both in British territory and beyond it. The teak forests in British Burma are the property of Government, and are carefully conserved. No care appears to be taken of those in Independent Burma, or in Siam, and it is to be feared that the destruction now going on must in a few years render it impossible to find large-sized timber in those countries, in such positions as to be available for the market. In the districts of British Burma, which were annexed in 1826, similar waste was allowed. It was only in 1852, when experience had shown the absolute necessity of guarding against indiscriminate felling of trees, that the Marquis of Dalhousie issued orders for the formation of a forest department in the province. First under Dr. McClelland, and afterwards under the present Inspector-General of Forests in India, Dr. Brandis, successful measures were adopted, for the conservancy of forests. This it was which led to the formation of a Forest Department for all India, which it is now acknowledged has been of vast benefit to the empire.

The growth of teak trees in British Burma is secured partly by planting in suitable localities, and by guarding against destructive agencies all young trees whether planted or of natural growth. The principal destructive agencies are:—Fire, which in the dry season, unless prevented, frequently spreads over hundreds of square miles, and kills young trees; parasitical plants; and the method of clearing ground for cultivation on mountain slopes carried on by the hill tribes, who indiscriminately fell trees and burn them in one mass. The latter enemy to forest conservancy is, perhaps, the most difficult to deal with, as there is great danger of exciting the ill will of the hill tribes by interference with what they have from time immemorial considered their right. Great caution therefore is necessary, and has been observed in carrying out measures necessary to check the destruction of trees by that means. Teak trees which have arrived at maturity, that is at the age of eighty to ninety years, are girdled two or three years before they are intended to be felled. The rise of the sap being thus intercepted, the trees die, and they become thoroughly seasoned while still standing. They are then capable of being floated down the streams and rivers without delay after having been felled. During the last five years there has been a material decrease in the yield of teak timber in the forests of British Burma. This will be seen from the following table of the actual quantity brought down during each year:—

	Tons.
1875-76 .....	46,597
1876-77 .....	46,431
1877-78 .....	39,081
1878-79 .....	22,763
1879-80 .....	17,585

It must not be supposed that the diminution in the annual supply brought to market indicates a diminution in the actual number of mature, or full-sized teak trees existing in the forests. The reduction proceeds from various causes, and it may

be confidently pronounced that the effect of the forest conservancy in British Burma has been to render available for public use a valuable natural product, while guarding against wasteful felling, which would, in a course of years, extinguish the supply for future generations. Various other timber trees are cared for in the forests of Burma, which is not necessary to enumerate. Cinchona trees have been planted, but the result, as yet, has not been favourable.

As regards the teak timber floated down the rivers into British Burma from the neighbouring countries, it will suffice to observe that the quantity is about four times that derived from forests in British territory. But, as already stated, as no conservancy is exercised in those countries, the supply, before many years, will probably be much reduced. Other articles exported from Burma are cutch cotton and petroleum, but they do not call for any particular remark. One abundant natural vegetable substance, however, promises to become utilised, and to add to the products exported to other countries. I allude to the manufacture of paper from bamboo fibre, which has been undertaken by Mr. Thomas Routledge. This enterprise will turn to good account a plant which grows rapidly in every part of British Burma; and there are many tracts where plantations of it may be formed for the object in view. The material would be exported in the shape of fibrous paper stock.

The inland trade of British Burma with Independent Burma and the Shan States is only yet in its infancy; but it has made great strides within the last few years. The progress during eleven years has been gradual, and is shown by the following figures:—

1869-70.		
Value of exports .....	£1,283,588	
Value of imports .....	905,308	

Total ..... 2,188,896

1879-80.		
Value of exports .....	£1,880,052	
Value of imports .....	1,983,354	

Total ..... 3,863,406

In order to show the value of the inland trade of British Burma in articles of British manufacture, and its progressive increase in eleven years, the following statement of the value of exports of textile and fibrous fabrics is given:—

	1869-70	1879-80
Cotton piece goods ....	£44,549	£191,821
Silk piece goods .....	9,025	168,936
Woollen piece goods ..	7,941	43,524
Cotton twist and yarn..	49,281	157,924
Total .....	110,796	562,205

The great bulk of the trade with Independent Burma is carried on by the River Irawadi. It is worthy of notice that, notwithstanding the unsatisfactory state of the relations of the British Government with the Court of Mandalay, trade between the two countries has not materially suffered. The great object of establishing and maintaining a direct trade with Yunnan has not been accomplished. The main obstacle to success may be attributed to the Chinese merchants settled in Burma, and to the Chinese local authorities on the border. The opposition of the former arises

from jealousy of foreigners, and what a people similarly circumstanced shows, losing a profitable trade. On the Burmese Government has been faithful treaty engagements with the Government of India, and with prudence and an aggressive conduct, which is certainly not to arise from the Burmese Government, the reason for doubting that the interest countries, as regards friendship and commerce, be maintained.

Means for ready locomotion and commerce are, of course, directly connected with trade and all material progress. When it was first occupied by the British Government was an entire absence of means for intercommunication, except by the rivers. In Tenasserim the great annual rainfall is a serious obstacle to the construction and maintenance of roads, the outlay necessary to abraded force being great, and the prospect of return or benefit in a sparsely-populated remote. In Pegu, the Irawadi has always a great highway, and in the delta which over ten thousand square miles, hundreds of navigable creeks form an excellent means for movement by vessels of all sizes, from canoe to barges of a hundred or more tons. But made roads for wheeled vehicles are few and far between. Main lines of metalled road have been constructed to a small extent. The total length of metalled roads does not exceed five hundred miles. The villages and distinct roads to connect the villages will yet occupy many years. A road has been built from Rangoon to Prome, a distance of 163 miles. The success of the line afterwards has been greater than could have been anticipated, considering the bulky nature of the produce carried, and the nearness of the river to the net earnings by the last account was 10 per cent. on the outlay. The chief source of revenue appears to be by passenger traffic.

The navigation of the Irawadi by the steamships of the Irawadi Flotilla Company continues to be maintained, notwithstanding occasional reports of unfriendly relations with Independent Burma. In 1879-80 there were made 129 trips up and down, between Rangoon and Mandalay. Bhamo appears to have been made. A line to connect the Pegu river with the Sittoung river completes the water highway between Rangoon and Toungoo, and is a great advantage. A railway between the same towns has been sanctioned by Government, and will be completed at once. The coast of British Burma has several ports are well-provided with light. There are seven, and one light vessel.

Among remunerative public works, the improvement of the Irawadi takes a prominent place. An exhaustive report thereon has been made by Mr. Robert Gordon, C.E., under whose direction the works now are. The object of the improvement was to protect cultivated and cultivable land from inundation. This has to a considerable extent been effected. But as is to be expected in a great river, having a rise of about 10 feet when in flood, and an extreme discharge during the rainy season, thirty miles above the delta, of two millions of cubic feet per

complications have arisen, and the question of the embankment is still under consideration. The lower part of the delta there are some miles of square miles which can be made safe by an embankment, and where the river is from the destructive force of current is reduced. Mr. Gordon has, with reference to the periodical rise of the Irawadi, the rainfall in the eastern Himalaya, and the discharge of the river entering the Brahmapootra in the north, in Assam below Sadisa, concluded that the Irawadi is the continuation of the Sanpo River. This is one of the few great questions in the geography of Asia which has still to be solved, and which has been a subject of controversy since the time of d'Anville.

After proposing to treat of British Burma, Mr. Gordon, however, would be incomplete without notice of the state of education. Elementary education of reading and writing is more generally diffused among the people of Burma than in the case in India, and even in some parts of Europe. This has resulted from the mental principles of Buddhism. For the Buddhists having originally protested against the exclusiveness in matters of religion, and regarding the acquisition of knowledge by those as their own duty; and having contended for the right of all to rise by personal merit to spiritual and secular eminence, and to inherit the reward by transmigration, the doctrine has been a general diffusion of instruction among masses of the people. Hence in Burma all children are taught letters; the national schools are the Buddhist monasteries, and the masters or the directors of the studies are the rahans or monks. There are also in some parts of the country lay schools, in which both boys and girls are taught. The rules of Buddhist monks prevent them from teaching girls; but female education is, in the higher classes, carried on in families, as in lay schools. The great importance of education being directed to the indigenous schools in British Burma will be seen from the number of pupils in the monasteries and lay schools, the number of which have agreed to receive Government aid. The number is 70,858 boys, and 3,330

girls in indigenous schools the medium of instruction of course is the vernacular language of the country. In the majority of instances the education does not extend beyond mere reading, writing, and arithmetic. In the monasteries there is usually very little of the latter, as it is not regarded as a part of religious knowledge, and is, in fact, a hindrance rather than a help to the progress of those who enter the path. The rahans, however, had the good sense to allow this kind of secular knowledge to be taught in their schools. In the monasteries those boys who are tended by their parents should become monks; but for years, while the great majority leave the monastic schools has been to avoid all connection with the religious teaching, and to the head monk of each monastery to admit pupils, in order that the secular studies should be systematically pursued, and the course be advanced than hitherto. For this purpose many books on arithmetic, geography, and

other subjects have been supplied, and are used. The monastic schools are far more numerous than the lay, there being in 1879-80, 2,693 of the former to 355 of the latter. But more difficulty has been formed in bringing the former into connection with the Government, and it is only in the latest report that it is stated—

"The monastic schools have made a remarkable advance, especially in the most important districts. Annual examinations of the monastic and lay schools are held, and prizes awarded. The girls in the lay schools are distinguished for their zeal and aptitude."

The Chief-Commissioner, in his resolution on the results of the year, observes:—

"After some years of only partial success, the Education Department has, mainly through the instrumentality of Burmese inspectors, got the teachers of monastic schools to accept with gladness, which now seems to be heartfelt, the visits, the inspection, and the guidance of our educational officers."

When it is remembered that the object in view necessitated action by Europeans, through native agency, in the denominational schools of an Asiatic people, and made it imperative to convince the heads of those schools of the entire absence of any wish or intention to interfere with, or counteract the religious instruction going on under the same roof to the same pupils, it will be felt that success could only have been attained by a rare union of tact, discretion, and earnest perseverance on the part of those to whom the work was entrusted. For the result, the Education Department of British Burma, under the direction of Mr. Hordern, may well be proud.

Of other educational work, it will only be necessary briefly to observe that numerous schools have been established in British Burma by American, French, and English missionaries. The American Baptist missionaries were the earliest in the field, and have achieved great results among the Karen people. The missionary societies have primary vernacular schools, and also secondary schools, in which the English language is taught. All these receive aid from Government, on account of the secular instruction given. The Government have also second-class schools in each district, while in Rangoon there is a High school, which has lately been affiliated to the Calcutta University. Each year pupils pass the University entrance examination, and some are now reading for the First Arts examination. Considering that the most populous part of Burma, which furnishes the great majority of students, has been a British possession for less than thirty years, it may be pronounced that the advance made in sound education has been satisfactory, and is evidence of the capacity of the people, and their desire for improvement.

I have endeavoured, in the time allotted to me, to place before you the several points in the present condition of a people differing in race, in language, and in religion, from the people of India; and I trust that the result will appear favourable to their moral and material progress. It is evident that the country and the people have before them a great future.

#### DISCUSSION.

Mr Henry Norman, K.C.S., said he had twice visited British Burma, and on each occasion had experienced the

greatest possible interest in doing so. The first occasion was more than 20 years ago. To speak of Burma, was to speak of Sir Arthur Phayre, for the two seemed to be inseparably connected. Sir Arthur Phayre was almost the first British representative in Burma. He started the province, and after many years of good government, left it in a fair way of that progress which had hitherto continued. Certainly, no province in India that he knew of had made such wonderful progress in the last 25 years, and it seemed as if that progress would still go on at the same rate. How much of that was due to Sir Arthur Phayre some of those present knew. It would be very interesting if some of the gentlemen who had spent many years in Burma, whom he saw present, would add to the information which had been given. Up to a recent date almost the only mode of travelling in Burma was by water, and that was accomplished with great comfort, and he hoped with profit to the steamboat company; but, within the last few years, railways had been started. At first there was a good deal of opposition to the project, and fears as to its result, but those doubts seem to have been quite dispelled by the experience already gained. He hoped the railway systems now projected in British Burma would be carried out, and he was quite sure they would be not only profitable to the State, but would conduce to the prosperity and progress of the country.

Mr. E. G. Man desired to thank Sir Arthur Phayre for his excellent paper, which was really exhaustive. He, as an old Anglo-Burman, recognised several gentlemen who had passed many years in the country, but if he might speak for them as well as himself, he should say that every subject had been touched upon in so masterly a manner by one who knew Burma so much better than most of them, that it would be superfluous to add anything. He would only make one remark on one part of the paper, and that was with regard to the statement that there was no communication at present, or were none last year, between Mandalay and Bhamo. He believed steamers had been running between those places up to the present time. He had also something to do with the timber business there, and could endorse every statement made with regard to the destruction which had taken place amongst the teak forests. Every year the size of teak timber was so decreasing that they had to go farther and farther inland for it, and even in the independent province of Upper Burma, the teak forests had been so worked out that, at the present moment, there was very little about, and in a few years there would not be a tree of any fair size to be got at. Of course, water carriage was of great importance in this respect, to enable them to get the timber down Rangoon, so that the merchants could sell it with any chance of realising a profit. With regard to the question of education, also, he could fully endorse Sir Arthur Phayre's statement respecting the experiments made by Mr. Horden and the Educational Department. There was no doubt that Burma was one of the best educated countries in the East. The people seemed anxious to learn; the monks taught them uncommonly well. He had not the slightest doubt there was a great future before British Burma.

Mr. Wm. Botly desired to make a remark or two on the influence of forestry on the climate and agricultural interests of the country. Only that day he was reading, in the Royal Agricultural Society's *Journal*, just published, a statement that the idea of an international exchange of reports on corn and forestry was first started in 1872, when, in Ponth, resolutions were passed in favour of agricultural meteorology receiving attention. That was brought before the Meteorological Congress at Rome, in 1879, and a Congress was held in September last year in Vienna, which was attended by 23 members, representing meteorology and agriculture of Europe in about equal proportions. Austria sent 8 representa-

tives, France 2, Germany 5, Hungary Denmark, Italy, and Switzerland 1 each. Great Britain were not represented, unless in our own case, the Meteorological takes the programme of subjects to late careful consideration, and had forwarded a series of replies to the work therein contained. For further inform the result of the Conference, he must refer to the *Journal of the Royal Agricultural Society*; too long to repeat. It showed the great interest throughout Europe in this question, and there is no doubt that it was of equal importance to Burma. He was glad that it had received the paper, and hoped the Government was possibly could to preserve the forests.

Mr. Proudes asked if Sir Arthur Phayre would be a likely field for research to ancient literature. Perhaps, at some future might give them further information indigenous literature of the country. He had been said about education, but he did not not with regard to old literature. He should whether it was much affected by the and or by the more modern Chinese under the if there were any traces of old Arabic literature believed also there was a wide field in anthropological investigation.

Mr. Thomas Bontledge said he was very an opportunity of adding a few remarks interesting and instructive paper, especially greatly desirous of utilising some of the products of Burma. For nearly thirty years he devoted his attention to the utilization of paper-making, and during the last six years had devoted himself especially to the paper present in Burma as a valuable paper-making. There were numerous other fibres indigenous to that country, which might be to advantage, but the bamboo received his because it grew in almost inexhaustible many districts occupying many hundred miles, to the exclusion of all other vegetation. The facility of its treatment was unexampled other fibres, such as the aloes, the plantain (*musa textilis*), &c., required a of manipulation, and, hitherto, no suitable had been devised for the purpose. The difficulty in utilizing them, because the sparsely populated, the labour requisite these fibres, which were chiefly suitable could not be obtained. A paper-making, from the exigencies of his trade, with the refuse of these fibres, and the expense of producing them as textile some years to come, be prohibitive. To the contrary, threw up long shoots every perennially—for 60 or 70 years at least established. All you had to do was to cut pass them into one of those streams the country abounded, float them down to them, and convert them into rough "steak" which he produced), and there was the paper-makers were so much in want of. It cost nothing but the collection, and then lation was sparse, he believed the difficulty over. Of course the population could not impenetrable jungle, but as it became population would follow, provided them for them. In a small pamphlet, some time ago, he drew a parallel between the asparagus, the main difference being that you out asparagus for five or six weeks, while season lasted several months. He believed ultimately form a good textile material, made rope of it; the houses they lived

their vessels, and nearly everything else was bamboo. An important Blue-book had lately been published by the Government of India, written by Mr. J. H. M. de la Harpe, of the Agricultural Department, giving a full and complete account of the materials suitable for paper-making in India. He had said, Burma was exceedingly rich in such materials as hemp, flax, jute, and the hibiscus tribe; and, like the aloe, required to be cultivated, and then dried, then steeped, or retted, and then hand-pressed, whereas the bamboo required nothing at all. The bamboo underwent was simply to crush it in a steam and boil it, and reduce it to a tow-like condition, when it could be compressed like jute or cotton, and it would then come into the ordinary freight-rate of those articles—about 45 cubic feet to the ton. This was done by a process he had patented in India. The bamboo, when dried and in its natural condition, was very hard and intractable, and, with any amount of simple crushing, could not be brought into a suitable bulk for freightage, which, after all, was a most important point, as affecting the cost of any raw material. A ton of produce, whatever it might be, did not occupy more than about 40 cubic feet as dead weight, but the bamboo, crushed to the utmost possible extent, would occupy 96 cubic feet, and if merely pressed in the ordinary way, even under a pressure of three tons to the square inch, would occupy 125 cubic feet, and, therefore, it could not come to this country as a raw material without some previous treatment. Treated as he proposed, its cost here would be about the same as the very cheapest material in the market. He was glad to say that he had received the very warmest support from the Government, and he was pleased to have this opportunity of expressing his acknowledgements to the Chief Commissioner Mr. Bernard, Dr. Brandis, the Inspector-General of Forests, and Mr. Ribbentrop, Major Seaton, the Forest Conservators, with whom he had been in communication. There were at first some errors, but on the whole they were now coming round to his views. He had now a special concession from the Indian Government in Burma, having chosen a province on account of its very favourable climatic conditions, particularly the large amount of all on the coast, which was as much as 160 to 200 miles per annum. In some parts there, rain or showers came months out of the twelve, which was very favourable to the rapid growth of the bamboo. Towards the north there was not so much rain. The soil was a rich loam, and in Arrakan there was an abundance of streams, which enabled you to float the stuff down to the port. (He produced a sample of crushed bamboo, "paper stock," "half-jute," and also paper made entirely of bamboo.) Mr. Arthur Phayre had referred to the enormous quantities of rice in the shipments of rice from Burma, and he mentioned that the first shipment of 3,000 tons was made by his friend Mr. Begbie, in 1856. In 1856, the shipments were 50,000 tons; and by 1860, 80,000 tons, while, last year, they exceeded 800,000 tons. He had tried rice straw for paper, but it was too costly, not good enough. For the cultivation of rice in Arrakan they had been compelled to introduce labour from Chittagong, but where things would grow to give the labour would follow. In the southernmost part of the province, he was informed there was an abundance of Chinese labour, and he had no doubt if sufficient inducement were offered to those industrious people they would make their way into other parts. Jute again showed the same wonderful demand as rice. In 1861, the imports did not exceed 27,000 tons, but last year they exceeded 100 tons. Esparto had developed just in the same way. In November, 1866, a paper was read in London by Dr. Royle, and the Society's *Journal*, containing the paper, was printed on esparto paper, which

he (Mr. Routledge) had then first introduced. In fact, in 1860, he was the only paper-maker using it, whereas now 200,000 tons a year were used. It was now getting very scarce and dear; it had been almost exhausted in Spain; the same thing was occurring in Algeria; and he feared the result of the French interference in Tunis and Tripoli would be to put a protective duty upon it from there. Everything, therefore, pointed to the desirability of developing the resources of India and Burma, so that we might be independent of foreign nations.

Mr. F. Barlow said he had just returned from Burma, but his tour only consisted of a three months' hurried journey through the country, so that he was not competent to say much on the subject. He was most heartily received by Mr. Bernard and all the officials, and it so happened that he was included in the census in some out of the way village near the frontier, from which in fact many of the inhabitants had gone over the frontier, fearing something was going to happen to them from the census papers being sent round. No one had alluded to the Burmese themselves; but they were the most charming and interesting people he ever saw, except the Japanese, whom in some respects they much resembled. The women were exceedingly pretty, and dressed in the most graceful and becoming way. The men were always cheery and nice, and you became friendly with them at once; very different from the natives of India. Whether Mr. Routledge would get over the labour difficulty he did not know, but he never saw a Burmese man work at all; he made the women cut wood and draw water, and employed Malagasy labour to gather his produce and till the ground. The inhabitants of the hills were of a more barbarous type; their cultivation consisted in burning down great tracts of forest; and at present the Government was trying to confine them to given districts, so as to preserve the teak. In one district when he was there, they came and asked leave to burn the forest, and were told they might do so if they would plant young teak trees and keep them weeded; but this concession they declined, knowing that when once the teak was planted, it would be strictly preserved. He might, perhaps, say a word or two on the question of opium. He travelled with the Chief Commissioner over a great part of Burma, and at every village he turned into the opium shops to see what effect opium smoking had on those who indulged in it. Those who came out were certainly horrible looking specimens, but when you asked one who, from an extraordinary look about the eyes, was evidently a confirmed opium smoker, how long he had taken to it, the answer always was, just two months ago, whereas he had probably been indulging in it for something like twenty years. It was a question, he thought, whether a total prohibition of opium in a malarious country would be wise. It was probably a useful drug in its way, and with it, as with most other things, moderation would do no harm; it was the excess which did the mischief. In Burma he doubted whether it was excessively indulged in to any great extent; but he had only gathered his information second hand.

Mr. Christian Mast hoped he might be permitted, as a native of a foreign country, but as an Englishman by naturalisation, to express the great pleasure he had felt in hearing about a foreign country like Burma, and the way in which this province seemed to be administered. He had often listened to papers read in that room, but rarely with such pleasure to an exposition of the mode of action in a British province as he had that evening. Very often they had heard about spreading civilisation in a manner which, if analysed, was anything but civilisation; but, to-night, they had heard that the real means of civilisation, namely, education, commerce, and trade, seemed to be employed in Burma, and the rulers seemed also to

enter into the spirit of the people, and not to run counter to their inclinations. He was much struck with the skill with which the governor seemed to have found out what the people liked, and to have escaped running counter to their religious feelings, so that for once the English race went hand in hand, he would not say with a semi-civilised race, because the Buddhists were highly civilised, and their civilisation was older than the English, but with an old race, and he hoped it would always be so.

Sir Arthur Phayre, in reply, said he was glad to hear it stated that steamers had gone up from Mandalay to Bhamo last year as usual, as it showed the trade with the frontier of China was likely still to go on, without any further interruption. The time he alluded to was 1879-80, when, according to his information, there had been no steamers. He had been asked, with regard to the literature of the Burmese, whence it was derived, and whether it had been influenced by the Chinese. As far as he knew, the ancient Burmese literature had not been influenced by China; but he spoke with great diffidence. He believed the Burmese were taught letters by Buddhist missionaries from India—probably from Gangetic India—but the present literature of the country might be said to be derived almost entirely from the Pali literature of Ceylon. From that, a vernacular literature had arisen; much as, they might suppose, the literature of England arose or had followed, from the Latin used in the Middle Ages. He had lately heard that remarkable discoveries had been made as to the extent of the Pali literature. While he was in the country, no researches were made on the subject; but, within the last two years, a German gentleman had been appointed Professor of Pali in the High School of Rangoon, and he had made some very remarkable discoveries as to Pali works existing in the country, and also as to translations into Pali from the Sanscrit, and again from that into the vernacular.

The Chairman said that, so far as his information extended, and certainly what Sir Arthur Phayre had adduced confirmed the impression, whatever discussions there might have been at the time, or difference of opinion as to Lord Dalhousie's proceeding in annexing the territory of Burma, the inhabitants had been only gainers by the process. Not only had their numbers more than doubled, but the commerce had quadrupled; in fact, there appeared to be all the evidence of improved government, and of the perfect freedom of development necessary to the welfare of the people. Certainly, if they had any doubts as to the mode of proceeding in different regions, it was a great satisfaction at least to know that there could be no question as to the results on the welfare and happiness of the people that came under our rule. Mr. Routledge had given some very interesting facts with reference to paper-making which had especially interested him, the "bamboo" being a very old friend of his. He had spent great many years in two countries where there was this singular state of things. In China, where rags abounded, they never used a bit of rag in paper, but it was entirely made of bamboo. In Japan, where also they had abundance of rags—in fact, they were a perfect drug in the market—they neither used them nor bamboo, of which they had plenty also, but the bark of the mulberry tree, with some twigs of other shrubs. The bamboo paper, which was well-known to artists many years ago, being specially favourable to fine proof impressions from copper-plate, was called India paper, because it was brought home in India ships; but it was really China paper, and there it existed to this day. That colossal empire, like other megatheria, moved very slowly, and had not shown the slightest disposition to use either rags or mulberry bark. The bamboo paper had one objection, that it was exceedingly perishable and brittle; it tore with the slightest effort, whereas that shown by Mr. Routledge was cured of this defect.

Japanese paper also, though often as fine as was almost as difficult to tear. Of course in China and Japan, the paper was made of mulberry bark, which again was really Chinese ink. The Chinese, with their marvellous development of industry in the last ten or twelve years, had now got vertical mills on the European pattern, and made a paper entirely of rags or rag mixed with other materials. The Chinese, on the other hand, went on with the bamboo paper as they did 3,000 years ago, as far as he could see, would go on doing so for as many years. Mr. Routledge's bamboo paper was made in many respects to that of the Chinese though he had been using it so long. He supposed it would be some time before they would have crushing machinery wherever the paper might be drawn from, in order to reduce it to some manageable condition for freight. They were rocked in bamboo cradles when they were fed with bamboo, and beaten with it when they were growing up; they lived under it in their homes, without bamboo one could scarcely undervalue a Chinese population could exist. There did not seem to be any trace of race hatred or religious feeling in Burma, to prevent harmony between the British and the Burmese, as there were in China, where the Chinese were continually being massacred, and the British burnt over their heads. He had not heard of that kind in Burma, and he presumed that the British were a more easily governed race, or had less prejudices. They must all rejoice at the good which Burma had made under the auspices of Sir Arthur Phayre; and, in conclusion, he offered a cordial vote of thanks to him for the very interesting paper which he had given them.

Sir Joseph Fayrer, F.R.S., said he was not usual to second the vote of thanks on this occasion, but he would ask leave to do so in order to give words. He could hardly express the great pleasure he gave him to be present that evening, when of 28 years ago, at which period he had been serving in Rangoon with Sir Arthur Phayre, being the first Chief Commissioner, and he had been a Medical Officer. At that time he could not have anticipated that at so distant a period he would have had the great gratification of seeing Sir Arthur Phayre in such excellent health, and of hearing him gratifying an account of the country he had governed. The population had been doubled more than doubled; the revenue had been doubled; everything had prospered. The nation was contented, and had preserved its individuality; religion was undisturbed; the people had been contented throughout the whole of British rule. They might indeed congratulate Sir Arthur Phayre upon this state of things, as no one could doubt that it was mainly due to his administration.

The vote of thanks passed unanimously, and the proceedings terminated.

A paper on "British and Upper Burma," by W. F. B. Laurie, was printed in the *Journal*, 11, 1880 (vol. xxviii, 640.) On p. 644, col. 1, "British Burma" should be read "Upper Burma."

## TWENTY-THIRD ORDINARY MEETING

Wednesday, May 25th, 1881; W. L. M. Memb. Inst. C.E., in the chair.

The following candidates were proposed for election as members of the Society:—

as Barnes, 77, Old-road, Middleton, near  
and Jessamine-house, Barton-on-Irwell,

Albert, 97, Finsbury-pavement, E.C.  
uel, 11, Queen Victoria-street, E.C.  
ard, Dartford, Kent.

omas Ruddiman, 108, George-street,

eric, 5, Porchester-gate, Hyde-park, W.  
., Froggnal, Hampstead, N.W.

liam Henry, 14, Essex-street, Strand,  
Vimbleton-hill, Surrey.

ng candidates were balloted for, and  
members of the Society :—

l Peto, M.A., The Holmwood, Bickley,

Ingham, West Ham Abbey, Stratford,

Maskall, 340, Brixton-road, S.W.  
um, Tower Chemical Works, Victoria

falcolm, Imperial-chambers, Bowalley-

um Purdie, 69, Ludgate-hill, E.C.

rned Discussion of Mr. Alexander  
er on "Electric Railways, and Trans-  
wer by Electricity," was resumed.

n said that amongst the numerous in-  
had characterised the past two or three  
plication of electricity to useful purposes,  
succeeded in inventing a process by which  
ly could be in two places at one time, and  
such an invention had prevented him from  
when the paper was read by Mr. Siemens,  
e admirable manner in which the proceed-  
ings were published, he had had an oppor-  
tunity of studying the paper. From one point of  
view it reflected the very greatest credit upon its  
author, as it was eminently a practical paper, and  
in the manner with a very abstruse, difficult,  
subject. Unfortunately, in the present day,  
there was a tendency to push practice on one side  
and theory and imagination very much to the  
other. It was especially the case with certain  
of the particular country, practice was thrust  
on the wildest imagination allowed to gallop in the  
papers with the greatest possible nonsense.  
Nothing in electricity that gave a latitude  
to this imagination: it was something  
quite different that at once, by its marvellous  
the telephone, the electric light, and  
other purposes, seemed to carry one beyond the  
of an age somewhere beyond the days of  
the ancients, and, as a result, they found, when  
the application of electricity was proposed, that a  
nonsense was talked and written. A few  
years ago appeared in the *Times*, written by some  
one who happened to be in Paris, where he was  
at a battery known as Faure's secondary  
cell described briefly this wonderful battery,  
giving night and day to Glasgow,  
and it with Sir William Thomson, it was  
said by a gentleman as "a little witch." This  
attracted attention, because people had been  
told that it was a process by which electricity  
could be carried about, and utilised for various  
purposes, when in Paris, being somewhat of a  
free mind, he (the Chairman) examined this  
battery, and came to the conclusion that there  
was a battery. The battery had a pretty high amount  
of electromotive force, equal to about 2½ Daniell's cells, but it  
had a very low internal resistance, and, there-

fore, able to give a considerable current. In all ques-  
tions of this kind where electricity was applied, a very  
important element was introduced, viz., the element of  
time. It was perfectly feasible and practical to produce  
a powerful current of electricity that would last a minute,  
or even three minutes, but for lighting and tramway pur-  
poses, or the ordinary power purposes in arts and  
manufactures, they wanted something that would last a  
very much longer time. This particular battery, that  
was supposed to store electricity, lasted but a short  
time; it gave a powerful current, it was a pretty thing,  
but it was not at present practical. Again, to illustrate  
the fact that imagination rather departed from practice,  
he might mention that, not long ago, a paper was  
read before the Society by no less an authority than  
Professor Perry, in which he said that he believed that,  
at no distant date, they would have great central  
stations, possibly situated at the bottom of coal pits,  
where enormous steam-engines would drive enormous  
electric machines; that wires would be laid along every  
street, and tapped into houses like gas, and registered by  
a meter; and that electricity would be used for driving  
machinery as well as for giving light. Now, judging  
from practice, he thought there was about as much  
probability of such a state of affairs arising in this  
country, as there was of being able to emulate the  
example of the young ladies mentioned by Bulwer  
Lytton, who put wings on their shoulders, and floated  
about beautifully in the air. There seemed to be in the  
present day a great tendency to ignore experience. He  
had been personally engaged in the practical application  
of electricity for over 30 years, and scarcely a day passed  
without his dealing in some shape or form with electric  
currents, consequently he might fairly claim to have  
some practical experience in the application of electricity;  
but on mildly venturing to suggest that a certain firm  
engaged in establishing the electric light was committing  
what might be regarded as a crime in the telegraph  
world—he was told that telegraph men knew nothing  
about electric light currents. Now, if anyone did know  
anything about electric currents and the disturbance to  
which currents were liable, they were telegraph men;  
and in the question of the transmission of force to a dis-  
tance, and the application of electricity to certain pur-  
poses, he thought there was some experience in the  
telegraph world which might be of service. For instance,  
it was proposed to transmit to a distance currents  
for the production of electric light and for the pro-  
duction of power. Many persons were aware that on  
previous occasions he had spoken of the application  
of the electric current to lighting purposes, and had  
thrown some cold water upon it, for the simple reason  
that the experience of telegraphists showed that it was  
impossible, with their present knowledge, to distribute  
electric currents through towns and other places, so as to  
carry out the dream of the projectors of electric lighting  
enterprises. The question of the transmission of power  
was an entirely different matter, and the difficulties in  
its way were of a totally different kind to those attach-  
ing to the unlimited division of the electric current. He  
maintained that the sub-division of the electric light  
with the notion of entirely supplanting gas was as futile  
and as absurd as the philosopher's stone. Although  
there were difficulties surmounting the transmission of  
electric current for the purpose of the transmission  
of power, still they were not so great, the chief  
reason being this, that to distribute light over a  
large area, or through a town or a number of houses,  
you must have a very high electric motive force;  
whereas to distribute the electric current for the  
purpose of producing power you did not want a high  
electric force. High electric motive force meant danger  
to the wires conveying the currents, as had lately been  
seen in the case of one of the companies now illuminating  
the City, the electric current having broken down the  
wires. Having said something on the merits of Mr.  
Siemens, it would now be as well to make what remarks

he had to make in criticism of him. He liked his paper, but he did not like his mathematics. He would not go very deeply into that point, because it would doubtless be considered a bore by the audience. The mathematical part of the paper seemed to be based on the labours of Dr. Frolin, but here was introduced a term which seemed to require some explanation, which he hoped Mr. Siemens would be able to give. That was the use of the term "effective magnetism" to express what was in reality electro-motive force. The electricians present would feel that that to apply a function of electro-motive force as an effect of the machine was to commit what logicians called an anomaly magnetism. Again, to explain something which was very simple in itself, he had been compelled to introduce what were called Foucault currents. These currents were currents created by the author to account for certain effects of heating observed in the armatures magnetised, but he thought what took place could be explained better by another well-known cause. It was shown in the paper that there were certain relations existing between the power put into one machine, and the power taken out by the other, and the whole practical value of the paper, and of the transmission of power by electricity, depended on the exactitude of these formulae. He did not question the formulae themselves—they were perfectly exact, but he wanted to enlarge them a bit in order to explain the anomaly which was found there, for which Foucault's currents had been invoked. If you had an armature wound with wire, revolving at a given velocity, and springs pressing against it to take up the current produced by the rotation of the armature between the poles of a powerful magnet, either a permanent or an electro-magnet, the wire from one of these brushes might go to earth, the other might be attached to the wire of one coil of an electro-magnet, and pass through the other coil, and then through a wire of any length to another similar apparatus, with a rotating armature and springs, and then to earth. In the one place magnetism was produced, and a coil of wire rotated with great velocity within the sphere of that magnet. The result was that currents of electricity passed along the line wire, it might be 100 yards or 10 miles, and then they came to another armature, precisely similar to the first; they passed through it, through the coils of the field magnet, where they produced magnetism, and established a field which produced mutual reactions between the currents of magnetism, and thus caused the second armature to rotate. [Mr. Proce drew a diagram on the black board to illustrate his meaning.] It was the rotation of the second armature which was utilised as power to turn machines, drive railway trains, and so on. He would point out that there was a certain relation between the power applied to the first machine, called the generator, and the power developed in the second machine, called the motor. The electric current developed by these machines was an exact measure of the power put into the machine, so that a proper instrument of this kind would be one of the most accurate and exact dynamometers a mechanician could use for small powers. Now the relation between the first machine and the second was given by a very simple formula. You could find anywhere the horse-power expended in the circuit by multiplying the electro-motive force by the current in the circuit, and dividing it by the resistance. In the second machine the electro-motive force was called  $E_2$ , and the formula showing the amount of work was—

$$W = \frac{E_2(E_1 - E_2)}{R}$$

In the first place there was the coil rotating very rapidly by direct application of mechanical force in the field of a magnet, which produced the electro-motive force  $E_1$ . This produced a current through the system, and this caused the second armature to rotate. But it rotated in the opposite direction, and by so doing it set up a

counter electro-motive force, and therefore it in the circuit was produced by the difference the two forces, and so they got the above. Now, since  $E_2$  is a variable, we can differentiate equation with respect to it, and by putting its co-efficient = 0, we obtain the maximum  $W$  could possibly be obtained. This occurs when

There was force put into the generator to drive in the motor, and it was impossible that the the second could equal the first, because there must be no current at all, therefore the rotation of the machine must be less than the first. On the of the rotation of the first must be pretty; there would be no work at all. It takes the formula he had given, that to produce the effect, the electro-motive force in the motor must be exactly half that in the generator. That to Mr. A. Siemens figures, they found that effect of every machine was at a maximum electro-motive force of the motor was half of generator, when the velocity of rotation of was half that of the generator, and when as done in the case was just half that of the. Hopkinson and others had shown that in dynamo machines you had 90 per cent. of converted into electro-motive force, and they it proved that the power given out by machine was half that of the first. was, if you put 5 h.p. on to the first you got a little less than  $2\frac{1}{2}$  h.p. in the motor half 90 per cent. was 45 per cent., as about what Mr. A. Siemens said was of force given out. He had shown them to be so, and, therefore, there was no more juggling up imaginary Foucault currents to the result. Mr. A. Siemens, however, was when he stated that it would still be common large stationary engines to work small at a distance, because large engines on  $2\frac{1}{2}$  lbs. of coal per h.p., whilst small ones six pounds. But there were difficulties to. As regards distance, that was nothing; distance could be easily got over, but serious difficulty when you came to a small motor machines. All these theories true when you were dealing with a driving another machine; but when you tal being laid along the streets, tapped into hot pipes, you introduced not one opposing force, or it might be 500, and here the practical the telegraphist came into play. They knew to introduce many instruments on one sin there was only one instrument on a circuit, at 250 or 300 words a minute, but when t apply intermediate stations and additional the speed ran down by the introduction counter electro-motive force, and the of was reduced accordingly. There were oth to which he would not stop to allude. conclude by again expressing his sense of Mr. Siemens's paper.

Dr. Siemens, F.R.S., said Mr. Proce, v known ability, had just shown that the power from the motor machine could not exceed communicated to the generator. That, he question which had been much dismissed a trifle, and Mr. A. Siemens had adopted course, of rather under than over-estimating which might be and had been obtained. It no means such a limit as 50 per cent. His undoubted accuracy had shown that you 60 or 70 per cent., and that the point of no was not limited to half the velocity; he agreed with Mr. Proce that there was a 3 velocities were equal theoretically, the one should be obtained, but the counter

se was also a maximum, so that practically lay between the two results of half velocity velocity. He had in his hand a report, received day, with regard to the working of the little Berlin, in which his brother put it, as the observation and measurement, that 60 per cent. effect was realised; but this was under very conditions. And it was one of the remarks connected with the electric transmission, that as the resistance to be overcome in the carriage increased, so did the force increase to the resistance. Thus, in going on a level, used to propel the train might be 10 h.p.; when the train ascended a gradient of 1 in 80, was the steepest on the line, then the power to drive the dynamo machine at the increased, and the power transmitted to the increased in a still greater ratio. Indeed, surprise to everyone who had investigated railway to see with what determined force the ascended the incline, with comparatively little of velocity. Of course, in order to overcome resistance, the velocity had to decrease. It d in the paper that the velocity of the train had ited to ten miles an hour; but, seeing the with which the train ran, greater speed had ved, and the carriages had gone to the distant ad back in seven and a-half minutes, which average speed of about twenty-five miles an difficulty had arisen, as happened with most tions, and this difficulty was of a most peculiar the Berlin railway, one rail conducted the towards the carriages, and the other took the station. Now, if a man passed over the level crossing, no harm was done, because he ot on only one rail at a time; but a horse lowed with four feet, he sometimes put one me rail and another on the other, and thus ed a most inconvenient shock, so much so, es decidedly objected to these level crossings, ame necessary to make some special arrange- avoid this inconvenience. It sufficed to put t the crossings out of circuit, and to connect ard and forward rail electrically. This experi- wed the practicability of the system, but his tirely agreed with him that it was not by any e supposed that the electric railway would omotive engines from our great thoroughfares. ric transmission of power would be efficacious, for local traffic, such as tramways, and also onveying minerals from the interior of a mine unk, and in exceptional cases for the trans- f heavy trains along rails. One of these cases ented by the St. Gothard Tunnel. The com- which that belonged were fully alive to all mprovements, and had requested them to work n for utilising the hydraulic power, which could great abundance near the mouth of the tunnel, assage of the train through the tunnel. By iphishment of that object, very great advantages gained; for, as those who had travelled through :enis Tunnel, or through the one on the line Alessandria and Genoa, were aware, great in- ace resulted from the emission of the products tion from the engines during the transit. If ould be sent through this long Alpine tunnel o force, a great inconvenience would be saved eenger, and at the same time a great saving effected for the company. Nearer home there e which would lend itself admirably to electric ion—the Underground District Railway. All o were in the habit of using that railway ed the facilities it offered in going to the rom it; but they also felt the inconveniences oducts of combustion choking the atmosphere. I been proposed for more thoroughly ventilating el, but they were only palliatives; the cure

would consist in finding a source of power without the inconvenience of combustion being carried on in the tunnel. A plan had been proposed for working the engines by compressed air, and he had nothing to say against it, but it did not do away with the necessity of having an engine nearly as heavy as the present locomotive. He believed if electric transmissions were tried on that railway in such a way as to make the rails act as the return conductor, making them all "earth," and fixing guide rails under the roof for the conveyance of the current, to be taken into each carriage by means of a metallic rope, great certainty of action would be obtained, and the trains would be propelled through the tunnel without fear of their being stopped midway, and at a very economical rate. These were the features of this innovation; that it lent itself to the conveyance of power to any reasonable distance, and that it could be applied without any of those inconveniences which now beset our locomotive traffic. He hoped that before long a trial would be made of the system, not, perhaps, on a very large scale at first, but sufficient to show its merits.

The Secretary said he had written to Sir William Thomson, with a view of having the secondary battery which had been alluded to shown; but Sir William informed him that he and Mr. Bottomley were engaged on a series of tests in connection with it, and until they were completed, he could not let it leave Glasgow. Otherwise, he would have been very pleased to send it.

Mr. Hale was not very sanguine that this method would answer for the Metropolitan District Railway. The line was not all tunnel, and he did not understand from Dr. Siemens whether he intended trains only to be taken through the tunnel by electricity, and then on by an ordinary locomotive; but, if so, that would be a great obstacle and delay. The locomotives were very heavy, and even the carriages weighed 12 to 14 tons each. Again, did he understand that the influence of the transmitted power would be as great 30 miles from the central station as a few miles only? It occurred to him that that was, at present, only theory. He should like to know the weight of the carriages on the Berlin line, and if the figures quoted of the cost were absolutely exact.

Mr. J. N. Sheolbred wished to add a word or two to what he had said last week in regard to the efficiency of electrical machines. Dr. Hopkinson had read a paper at the Institution of Mechanical Engineers, as to the efficiency of electric machines, as Mr. A. Siemens had stated; but a year later, Mr. Gray, of Silvertown, had also given the result of a similar series of experiments, which he had carried out during the interval with a Gramme machine, the one used by Dr. Hopkinson being a Siemens. On the wall were two diagrams, showing the results of each series of experiments, and it would be observed that there was a wonderful similarity between the curve shown as developed by the Gramme machine, and the curve shown by Mr. Siemens, as the result of experiments carried out on a similar machine by Meyer and Auerbach. The peculiarity about it was the sudden dip at a certain point, near the end, which Dr. Hopkinson suggested must have been due to a slip in the driving band, or some accident of the kind. Mr. Gray, however, felt quite certain that such could not be the case, but "that it was due to the magnetism of the field magnets falling off, after the external resistance had been reduced beyond a certain point; and was somewhat analogous to the action in a battery due to polarisation. This effect would be produced in a Siemens's machine only when the external resistance, had been still further reduced than in the case of a Gramme machine." The curve of Dr. Frölich's experiments on the Siemens machine also confirmed the accuracy of this statement. With regard to Mr. Preece's remarks, he had long hesitated about accepting the dictum that the loss of power must neces-

early be 50 per cent., and he must now decline to accept it, especially as the opposite view was confirmed by the remarks of Dr. Siemens and Professor Ayrton. Generally, two machines of similar construction had been used, but if instead of that the secondary machine was of a lower electro-motive force, you would thereby increase the difference on which the effective result depended. Some time ago he had occasion to try experiments with different sized machines, and he at first drove with a large machine using a large amount of mechanical power, but with a low electro-motive force; whilst the secondary machine, being smaller, had a higher electro-motive force. He then reversed the machines, and drove from the smaller machine, which required a smaller amount of energy, but which possessed in its internal construction a higher electro-motive force than the bigger machine; and the same amount of work was then done with a smaller expenditure of mechanical energy. Consequently, in the second case, where a machine with this lower electro-motive force was the driven one, you got a better result than in the first instance. The main point was to get as great a difference as possible between  $E_1$  and  $E_2$ , but you could obtain that not merely by difference of speed, which could be obtained with two machines of the same kind, but also by employing two machines having each a different electro-motive force. Speed was a matter which settled itself according to the load. A high speed in the generator meant a large amount of power, a low speed in the motor meant that it was doing a large amount of work. What Dr. Siemens had said about the effect of inclines on the railway, came to much the same thing. It had been explained by Dr. Siemens in a very interesting way in a paper read before the Society of Telegraph Engineers. The difference of potential between the two machines was at a maximum when the second was at rest, the moment it started, it went at a tremendous velocity, and until they settled down to work, it increased in velocity. The effect of ascending the incline was to throw more work on it, diminishing its own speed, and, consequently, the augmenting potential of the other one. He would refer anyone who was interested in the subject, to this paper of Dr. Siemens, where it was most clearly explained.

Mr. Donathorne said he had noticed a spark at the point of contact between the wheel and the rail last week, and he wished to ask whether there would not be a loss of power in consequence.

Mr. Bright (Mayor of Lomington) asked whether there would not be a danger in wet weather of the electricity passing from one rail to the other, in the same way as when the horse stood upon it.

Mr. Dignall asked whether this system would be applicable to large ocean steamers and purposes of that sort.

Mr. Clements thought there was not any great difficulty in understanding this subject, especially as there was a railway now in operation, which would give great encouragement to the opening of other railways of a similar kind, which he hoped might be tried. They all knew the great difficulties which the present railway schemes had to contend with at their inception, especially from the immense Parliamentary expenses, and perhaps these might be saved in the case of electric railways. He referred to the various difficulties which beset ordinary railways, and thought the present gauge was too wide. It would also be a great advantage if the power of water could be utilised as had been suggested.

Mr. Crompton, being called upon, said he had used the transmission of power by electricity experimentally in lectures, and for such purposes, and had driven machines at a distance, but he had not measured the power employed at the generator, or given out at the motor, and without such experiments he did not feel that he

could add any valuable information to what was before the meeting.

Mr. A. Siemens, in reply, said he would ask the audience very long with replying to detail the theoretical part of the paper, and said as Messrs. Ayrton, Schoolbred, and Preece, when he began with, it was true he had applied the little formulae to electro-motive force, that was he already had two letter E's, and he thought it clearer if he followed the example of Dr. Hall called this electro-motive force unit M, it was not to have too many letters E in the formula. Preece had very ably explained how he wrote equation he had given, but he had overlooked same equation had been given in the paper, diagram on the wall showed that the work of second machine was equal to a constant unit the electro-motive force of the second machine by the current. The current was equal to the motive force of the first machine, less the electromotive force of the second, divided by the resistance you replaced C, by this expression, the equation be the same as that given by Mr. Preece. hurried over the theoretical part of the paper he did not want to be too scientific in a Society to applied sciences. As regards Mr. Schoolbred's suggestion that the difference should be as possible between the two machines was as according to mathematical rules the maximum when  $E_1$  is exactly half of  $E_2$ ; force could not agree that the second machine have as low an electro-motive force as Professor Ayrton and Mr. Schoolbred use machines with permanent magnets, instead of machines, but he could not agree in that they all knew that these magneto machines known for over 40 years, had never been transmitting power. That fact alone showed they were not fit for the purpose. exciting all dynamo machines by separate magnets had also been treated in the paper, by Dr. Preece rather doubted the presence of the currents, and seemed to think that I or himself was the originator of them, was not so. In some machines they bobbins revolving in a powerful magnet they began by protecting those bobbins them in shape by putting small copper plates side, and they then found that simply two machines, without closing the outer circuit great power, and that these plates got heated, although there was no current passing through the wires of the bobbins simply the Foucault currents circulating in plates on the two sides of the wire, which heat, and made the exertion of power near same thing happened if, in a dynamo in iron armature was quickly moved in a field. He might also say that the Siemens had alluded to of having separate wires suspended overhead, instead of using for the two leading wires, was going to be tramway in the suburbs of Berlin, where a single wire would run on the wire and be connected ordinary tram-car by a metal rope, the other the tramway serving as a return conductor. at once answer one of Mr. Hale's question an electric railway were to be applied to suburban lines, the wires connecting the carriages would be suspended in the tunnel the roof, and between the tunnels they supported on poles. It had been said that be very difficult to distribute the current because you had not to deal with the question of having one machine generating and another utilising it, but you only lot of machines, some going and some

into the details, because he wished to be as practical as possible. As regards the Metropolitan Railway, it would be possible to take one of the small engines shown to pull a heavy train, but it was quite practicable to construct more engines for the work. Dr. Siemens had at that time a scheme on foot for running the St. Gothard Tunnel by electricity; they would have to have a locomotive to haul the locomotive at the mouth of the tunnel, use the same rolling stock; the electro-locomotive would be just as heavy as the locomotive, have the same adhesion, and there was no more passengers in the train. He understood that the locomotives were often changed on English railways in the case of the express which went to London; passengers took refreshments while the train was on; if, therefore, the time lost in changing locomotives were the only difficulty, they could have a refreshment-room at the mouth of the tunnel, when no one would complain; but, of course, for the Metropolitan lines, special rolling-stock could be used, and a special dynamo machine could be put on the line, and then trains could be made up in 1/2, 1, long or short. Of course, he could not run an electric train on the Metropolitan Railway, or even lay a full scheme before the public for the purpose; what he wanted to prove was the electric transmission of power had made a great progress during late years, and was under certain circumstances, and would no doubt be able to run the distance from the stationary engine, in a circuit was so small that it would make no difference if it were extended to thirty miles; regards the cost of the railway, that was the subject of the paper where he had dealt with different facts. The items, of course, were the greatest possible accuracy, but according to prices, where labour, and also iron, he was cheaper than in England. Another question was what would happen in wet weather. Mr. Lichterfelde had worked exceedingly well in wet weather. It had excited a great deal of interest, a deputation from the Society of Railway Engineers in Germany paid a visit to it, and fortunately in wet weather, when the rails were rusty and quite damp. The tension, however, of the wires was so very low, the resistance of the wet rails was still sufficient to keep the insulation, and the current ran along just as if it were dry. The overhead conductors were used, they were insulated, as the present telegraph lines at that time would have still less influence. As to the little machine showing sparks on the wheels due to its small weight, if it had the wheels would have made better contact, and no spark would have been seen. He understood that the electric transmission of power would be used on steam-ships because you must have some work for the primary engine, and a secondary engine to work the propeller, and if you had a small engine on board it would be more advantageous than the screw. The only other way of doing it would be to have a stationary engine on the shore connected with the ship by a cable, and it would be very awkward if the cable broke. It was pointed out by several speakers that if the secondary engine was turned with the same speed as the first, equal E.M.F., and there would be no current. A practical turn of mind, he thought it would try that, and so he had two machines tried, running at 684 turns per minute, the secondary engine making 684, ran 730, or 46 turns quicker than the first, and at that time there was a current of three webers going through the system. He had a brake applied to the second machine

which brought it down to 652 revolutions, a little slower than the first, and then the current increased to 7.8 webers. Then he had another experiment made, because he thought it might be objected that the first machine had a greater or smaller electro-motive force than the other; he therefore reversed them, and made the secondary one the primary, it was then driven at 682 revolutions, there was a current of 4 webers, and the second one ran at 755, or 73 quicker than the other. Then, again, he applied the brake, and he found the primary machine ran at 690, and the second at 684, there was a current of 7.8 webers, and a little bit of work done, .07 h.p. This seemed to contradict theory; but he thought the explanation would be found in the mode in which the brushes were applied to the revolving armature; because, when applied in the most efficient manner, for the machine turning in one direction, they would be not properly placed for obtaining the greatest effect when the direction was reversed. Therefore it was possible to drive the second machine a little quicker than the first, although the theory seemed to prove that it was impossible.

The Chairman, in proposing a hearty vote of thanks to Mr. A. Siemens, for his able and practical paper, said the weight of the carriage was not of much consequence; if the carriage weighed 20 tons, it would require 160 lbs. to pull it; and inasmuch as by the system of electro-dynamo machines, they could, without difficulty, transport to a distance of 20 or 30 miles, as the case might be, from 5 to 10 h.p., it was quite evident that whatever might be the weight of the carriage, Siemens's currents would be strong enough to move them quite fast enough. He was afraid that Mr. Alexander Siemens, at one time, was going to upset his own theory, for he proved that, when the machines ran under certain circumstances, these ran at nearly the same velocity; in some instances, the second machine ran faster than the first, but he took care to let it be known that the second machine was doing no work. Now, it was well known that one could not have his cake and eat it too, and if you had a machine, as the second machine, driving a wagon, the power could only be utilised at the expense of power absorbed elsewhere. If you put a 5 h.p. into the machine at one point you would, under the circumstances, only get 2 1/2 h.p., the other 2 1/2 h.p. being absorbed in heating the machine. Notwithstanding what Mr. Shoolbred had said, he was prepared to stand on the formulae he had given as being correct, according to experiments which had been made, and, moreover, it accorded with facts. The advantages in favour of electricity were the ease with which the power could be transported from place to place, the cheapness with which it could be utilised to different purposes, its freedom from danger, and, above all, it fulfilled to the very highest degree one of the principal duties of the engineer, namely, the utilising for the benefit of mankind the waste forces of nature.

The vote of thanks having been unanimously accorded, the meeting terminated.

### ART FURNITURE EXHIBITION.

The private view of the Exhibition of Works of Art applied to Furniture, promoted by the Society of Arts, in connection with the Fine Arts Exhibition at the Royal Albert Hall, was held on Saturday, 21st inst., and the Exhibition was opened to the public on Monday, 23rd inst. The objects are arranged in a series of twelve bays in the galleries round the hall, each bay being arranged by a particular firm.

Bay No. 1 contains a cabinet of carved walnut-wood, an octagon table of the same, a cabinet of satin-wood, and chairs, exhibited by Messrs. J. G. Grace and Son, besides stained glass by Messrs. Heaton, Butler, and Bayne, and china by Messrs. Minton and Co.

Bay No. 2 contains a screen showing the side of a room decorated in the English style of late 18th century, with silk in the panels, and an oval mirror in a gilt frame of same period on the centre of panel; satin-wood cabinets, pole-screens, and arm-chairs, marqueterie writing-table, mirrors, &c., exhibited by Messrs. Morant, Boyd, and Blanford; also three dishes of gold lustre-ware, by Mr. William de Morgan.

Bay No. 3.—The walls and ceiling are decorated in the Louis-Seize style, and the bay contains a cabinet and chimney-piece in the Oriental Greek character, composed of boxwood, ivory, pear, ebony, and other woods; several other cabinets, tables, chairs, &c., and various specimens of old Japanese lacquer, and Chinese and Japanese ornaments, exhibited by Messrs. Jackson and Graham; also wrought-iron dogs, by Feetham and Co., and combination gaseliers in ormolu, and cut-glass, by Messrs. F. and C. Osler.

Bay No. 4.—Messrs. Gillow and Co. show part of a room in the Italian style. The walls are hung with green velvet, the embroidered borders executed from designs of the firm by the School of Art Needlework. The Oriental carpets and curtains from Messrs. Vincent Robinson and Co. The chased metal works and ornaments by Messrs. Elkington and Co. Painted vases and tazzi, in the Italian style, by Messrs. Minton and Co.; and the Doulton ware and painted plates, by Messrs. Doulton, Lambeth. The stained glass window from the Royal Stained Glass Works, Windsor, and cut-glass, and chandelier, supplied by Messrs. Webb and Co., of Stourbridge. Messrs. Gillow exhibit mantelpiece, carved walnut secretaire, satin-wood cabinet, tables, seats, tripods, &c. Wood carvings of birds, of a Shakespeare cabinet, and of the head of Shakespeare, by Mr. W. Perry.

Bay No. 5.—Messrs. Holland and Sons exhibit a *dressoir* for dining-hall, of oak, inlaid and relieved with gilding, the centre of canopy surmounted by a tablet with carved subject, and mottoes from Pericles, the metal work entirely of hand-wrought brass, designed by the late B. J. Talbert; a cabinet in ebony, designed and partly executed by Barbeti, of Florence, and a writing-table.

Bay No. 6.—Messrs. Howard and Sons exhibit a special treatment of wall elevation and embroidery, cabinet work and parquet flooring. The Barberini and Milton vases in carved glass, are exhibited by Mr. P. Pargeter.

Bay No. 7 contains a specimen of wall decoration of the 18th century, after the style of the Messrs. Adam, a mahogany inlaid sideboard, and cylinder writing-table of the same period, a pianoforte case of marqueterie work of Louis XV. period, mahogany writing-table of the 18th century, after "Chippendale," and various specimens of carving and gilding, all exhibited by Messrs. Wright and Mansfield.

Bay No. 8 contains *dressoir*, mantel-piece, chairs, and other decorative furniture exhibited by Messrs. Collinson and Lock.

The corridor contains specimens of Doulton ware, exhibited by Messrs. Doulton and Co., consisting of terra-cotta panels, designed and executed by Mr. G. Tinworth, decorative panels by Miss Jane Atkinson, tiles and plaque by Mr. Edward Sears; also stained glass by Mr. Sears, and Algerian carpets worked by hand by S. Moline, of Algiers.

Bay No. 9.—Messrs. Gregory and Co. exhibit a collection of cabinets, tables, chairs, &c., in solid rosewood, of the modern English school. Turkoman tapestry, curtains, and *portières* of a special manufacture, suitable for rooms where Oriental carpets, &c., are used.

Bay No. 10.—Messrs. Shoobred and Co. exhibit

carved cabinets, tables, mantelpiece, and furniture.

Bay No. 11.—Messrs. Johnstone, Jeans exhibit carved Italian walnut buffet, and a chair to correspond, walnut panelling for side room or hall, and specimens of stained glass. In this bay is shown by Messrs. Minton and the metal work by Messrs. Perry and Co.

Bay No. 12.—The School of Art Wo exhibit a copy of 18th century English piece, 3 feet deal moulding, executed by L. Irwin, two pilasters by Miss F. E. M. Young, the fittings by Messrs. P. Co. Mr. Sidney Phelps exhibits panels of two pairs of sconces, and a pair of iron-work. Mr. F. Gleeson exhibits an mounted with Meehlin lace, and carved mother-of-pearl, ivory, tortoiseshell, and ebony. Messrs. Morton and Co., of Edinburgh examples of Tynecastle tapestry, a new covering of walls, &c., the invention of M. Morton. Mr. Thomas Jacob exhibits two cabinets.

With reference to the award of the Soci and certificates, it has been decided that the designers and art workmen who have in the production of the art manufactures shall be given to the jury appointed medals and certificates of the Society of A the names of those to whom the awards are published in the *Journal*.

The Council of the Royal Albert Hall h present each member of the Society of Art transferable season ticket, and any member such ticket can have one on application to Society of Arts.

## THE PROPAGATION OF SPONGE CUTTINGS.

By C. G. Warnford Lock.

In a recent report on the Bahamas December 31, 1880, p. 102), Professor I called attention to the account of the of the Austrian Government to improve spon the Adriatic, published by Dr. Emil von the Transactions of the Zoological-Bot of Vienna." The following abstract fro original will, doubtless, have an intere readers of the *Society of Arts Journal* :—

The history of the experiments, Dr. Mi misses in a few lines. Professor O. Schmid in the *Wiener Zeitung*, and in his work on sponges (both in German), expressed a co if a perfectly fresh sponge were cut into s and these were again placed in the sea, the and in time become perfect sponges. Thi the test by an experiment conducted i Socolizza, on the north-east point of the ial commenced in 1863, and concluded in No Success was rendered impossible by the t turbulence of the locality with fishing nets actual robbery of sponges and apparatus worm, which contributed to the mischief the woodwork used, was harmless in co the determined opposition of the local pop by a deep prejudice against the innovatio fortunate circumstances, however, did no accumulation of a mass of valuable info calculated to form a basis for the rep attempt under more favourable circumstan

The most suitable season for commencing gation is the winter. The growth of the the healing of the cut surfaces, proceed slowly in winter than in summer; but a l

dangerous, by reason of the great tendency of sponges to undergo rapid putrefaction. In winter, a sponge may remain dry for several hours; in summer, it is ruined in a few minutes after leaving the water, especially if not constantly supplied with fresh water. Buccich placed some sponge cuttings for eight days in a shady airy place, at a temperature of 7° R. (45° F.), in the month of February, yet all grew.

For healthy, choice should be made of bays sheltered from waves and currents, but not quite still; the bottom should be rocky, and clothed with living algae; there should be a moderate ebb and flow of the tide; the neighbourhood of the mouths of brooks, and subterranean springs must be avoided. The colour and liveliness of colour of the marine algae are indications of a suitable spot. The worst enemy of sponge culture is mud. Under certain circumstances, the use of the bay by means of a chain across the mouth is to be recommended.

Sponges chosen for cutting must be gathered by experienced hands, with all possible gentleness. They are raised either by tongs or by drag-nets. One arm of the net is fixed to a long stake, the other is movable and can be advanced towards the first by a noose, drawn over the stake by the collector; objects coming to the crimped ends of the tongs are thus held and can be drawn up to the surface, of course only to a certain depth, such as the eyes and the stake can reach. The sponges must either (and this is the ideal point) be taken up with their roots entire, or must be torn from them, whereby a prejudicial or serious wound may very easily be inflicted. As pointed out at Lussini and Lesina, that when the men of O. F. Müller's or Ball's drag-nets, or even resembling the "trawl" of the English and the deep-sea fisheries, the sponges were nearly brought up in good condition. It is also very important, when collecting sponges for subdivision, to make a certain selection, as the malformed and worthless specimens are as well adapted to the purpose as the best shaped. Such of the latter as are left up should be left intact, and prepared for use.

The raising of sponges by means of the tongs has the additional objection that the operation can be carried out only when the surface of the sea is perfectly smooth. The sprinkling of oil on the surface is entirely effective for the purpose of rendering it smooth. Buccich, therefore, devised a simple apparatus, described as follows:—A tin box, 32 c.m. (12½ in.) long, with a glass plate fixed in the bottom; on placing the box on the surface of the water, the bed of the sea is visible. [The Greek sponge-fishers make use of a wooden cylinder, 37 c.m. (14½ in.) in diameter, 12 c.m. (19½ in.) high, with a glass plate in the middle, and sink it half-way in the water. The Spanish and pearl-fishers in the Bahamas and Panama use a closely similar apparatus for a like purpose.] Buccich found that it was not judicious to throw the sponges gathered from time to time into one common heap, there to await the cutting operation, as they were easily injured, by the pressure and by the heat of the sun. He therefore adopted the plan of keeping them temporarily, with wooden pegs, to the inner bottom of a fish-basket, fastened to the tow rope at whence the fishery is being prosecuted. If a sponge is injured, the damaged portion must be cut off; the rest is pegged up, either in its entirety, or cut into pieces.

In the cold season of the year, when the sponges are freshly caught on the spot, and at once made into cuttings from them; whilst in warm weather, it is necessary to wait and see what signs of putrefaction make their appearance. This reveals itself by the dullness and softness of the sponge part. When it happens, further observation, after cutting off the diseased portion, to see whether the putrefaction has spread. Small

sponges are usually totally destroyed when once attacked; in large ones, a limit may sometimes be set to the mischief.

The dissection is rapidly performed, either with an ordinary knife, or, as Buccich found, better with a fine saw-like blade, which is much less liable to injury by the foreign matters so abundantly found in sponge. The sponge is laid upon a smooth wooden board, moistened with sea-water. The size of the cuttings is usually about 26 c. mil. (1 cubic inch). It is well that each cutting should have the greatest possible area of uninjured outer skin. The cuttings are placed directly in the spots where they are intended to resume growth.

A healthy piece of sponge firmly attaches itself to any surface with which it comes into intimate contact in a short time. Cut sponges grow together again. The attachment takes place most rapidly when the pieces have but one cut surface, and this is laid upon the support—wood, stone, &c. During perfect calm, for at least 24 hours, it is possible, according to Buccich, to plant the cuttings upon the stony sea-bottom itself, and they will hold. He saw pieces that were merely cast into the sea on an ordinarily suitable rocky bottom, during perfect calm, attach themselves and grow. Thus enlightened as to the natural habits of the sponge, Buccich prepared stone slabs, 53 mm. (2 inches) thick, as a foundation. These he perforated with holes, and fastened the cuttings to them by wooden pegs driven into the holes; but it became evident that the mud and sand of the sea-bottom, perhaps also excess of light, were inimical to further growth, and the necessity for preventing or minimising these two evil influences has been shown by all experience. Preference will always be given to stone as a foundation, it being the natural ground, cheap, and not attacked by the teredo. Originally Prof. O. Schmidt employed perforated wooden chests, on whose inner side, the cuttings were fixed by means of metallic or wooden tacks. This extremely simple arrangement was found unsatisfactory, as the chests, when sunk in the sea, became filled with sand, and the holes got stopped up and ceased to admit light. The sponges acquired a white sickly look. The attaching of the cuttings by metallic pegs is objectionable; all cuttings thus treated were much slower to resume growth than those pegged with wood. The rust which soon forms on the metallic nails prevents the sponge from taking a firm hold, so that the immediate portion, and possibly the whole cutting, is ruined. Lattice frames, having the form of floating tables above, and with the sponges attached beneath, have also been tried. Professor O. Schmidt also suggested merely tying the cuttings to strong suitable strings. By the first plan, there was too much shade; by the second, too much light; and possibly some mischief was done by the fine matters drifted over the surface of the sea, and accumulated as a deposit of the compound vaguely known as "dirt." Buccich first constructed an apparatus composed of two planks crossing each other at right angles, with a third plank as a cover. This was so far successful that the cuttings were exposed on all sides to the action of the sea, and assumed the desirable round form. He then made a modification of this apparatus, consisting of two boards, 63 c.m. (24½ in.) long, and 40 c.m. (15½ in.) broad; one forms the bottom, and the other the lid, and they are held parallel one over the other at a distance of 42 c.m. (16½ in.) by two short stays, some 11 c.m. (4½ in.) apart. In the space between these stays, stones can be placed as ballast; on the top of the cover, is a handle. In both planks, holes are bored at 12 cm. (4½ in.) apart, or 24 holes in each. Buccich fastened the cuttings not simply on the apparatus, but on sticks which were driven into the holes of both boards. As material for the sticks, he chose before everything the common Spanish cane, whose siliceous rind is proof against the attacks of the pile-worm. The sticks were 42 c.m. (16½ in.) long, and bored through at distances of

12 a.m. (4½ in.), the lower end being split. On each stick, three sponge-cuttings were fastened in such a manner that they should lie over the bore-holes, through these, wooden sticks were thrust, and each cutting was thus fixed. [It is a matter of great regret that no illustration of these several apparatus was published in the original.]

When the sponge-cuttings are to be pegged only with wooden nails, a triangular stiletto will suffice for piercing the sponge. When adopting the method of fixing by sticks, such an instrument is not suitable, because much too great force would be required to make an opening to admit the sticks. Forcing and squeezing cause a loss of *serreds*, the minimising of which is the first rule that governs all manipulations of sponge. Buccich bored the cuttings with an auger with toothed edges, 6 mm. (¼-inch) broad, fixed to a vertical wheel, driven rapidly by a little pulley. While one hand quietly presses the sponge against the borer, the other turns the wheel. In a few seconds the operation is concluded. The bore-hole is clean, the fibres are not torn, and the *serreds* does not run out. When a stick is filled with cuttings, its split end is thrust into one of the holes in the support, and a wedge is driven through the slit. As each bottom and top takes 24 sticks, carrying three cuttings apiece, one such apparatus will accommodate 144 cuttings.

During the whole manipulation, until the arranging of the sponges is quite complete, they must be repeatedly and gently moistened with sea-water, especially in summer. When an apparatus is furnished, it should be sunk at once in warm weather; in winter, as before remarked, a little delay does no harm. The apparatus may be most conveniently let down and pulled up by means of a small anchor. The depth may be 5 to 7 metres (15 to 22 ft.).

The suspension of the apparatus from a support, Buccich does not consider necessary. All woodwork must be well tarred. This is not a perfect remedy, but is the only temporary precaution available against the pile-worm. In the Bay of Scoglizza, it was proved that the tarred portions even were destroyed at last. The *teredo* not only increases the amount of capital necessary for repairing the damaged apparatus, but also depreciates the condition of the cuttings, as the pegs or sticks fall out, and the sponges are destroyed. The most rational mode of procedure would therefore be to avoid wood altogether, and to make use either of stones, with suitable precautions against mud and direct light, or to employ iron in the construction of the apparatus recommended by Buccich.

If the cuttings hold fast after three or four weeks, the propagation is secure. A characteristic feature of the cuttings is their tendency to assume a round form. To facilitate this on every side, is the chief aim of Buccich's system of supporting on sticks. As to the rate of growth of the cuttings within a certain period, no rule can be given, on account of the varying conditions. Buccich remarked that the cuttings in the first year were two or three times as large as they were originally. He further remarked that the cuttings grew better in the first and fourth years, than in the second and third—a point evidently regarded as doubtful by Dr. Marenseller; and it would seem that though some specimens may have attained a considerable size in the fifth year of transplantation, still a term of seven years is necessary to produce a marketable and profitable article. Dr. Marenseller also mentions the fact that, besides being beautifully formed and rounded, the cuttings retain these qualities, and perfect health, with increasing age.

In conclusion, Buccich proposes the question whether the undertaking can be made profitable, and answers it in the affirmative. He is of opinion that, with due care in the operations, the cuttings will thrive, and the loss need never exceed 10 per cent., including all outlay.

5,000 cuttings at about 300 gulden (the gulden worth nominally 2s., really about 1s. 8d., or 18 pence = £25), and the loss at 10 per cent., there is a drop of 4,500 sponges at the end of seven years, the value of which Buccich places at 900. Dr. Marenseller considers this price far too high; the wholesale merchants in Trieste give an average of 8 gulden, and a maximum of 10 gulden per Pelmatic sponge. The sponges must be of a certain size, such as will not with certainty be eaten in seven years. Finally, allowance must be made for the fact that the sponges grown on sticks are considered commercially inferior, and that their value, on account of the central perforation, is one third that of naturally grown sponges. The profit seems larger if there were not so long an interval between the outlay and the harvest; in other words, growth of the cuttings were not so slow. 3 years' suspense is a great deterrent. To this is added, that in order to maintain a continual production during the seven years from the commencement of annual outlay, equal to the first, is necessary, the apparatus is not so simple that any dweller on the coast can make it for himself, and wood is not available on account of the pile-worm. Dr. Marenseller, therefore, concludes that the propagation of sponge by cuttings is not to be recommended to people without capital, but is more suited to the attention of a capitalist, or an association of capitalists, and should be conducted on a large scale. [The great amount of money in Austro-Hungary must be borne in mind in weighing this opinion.] It would be a matter of encouragement did we possess the knowledge to augment the growth of sponge under natural conditions, even though it were no more rapid than in the case of the cuttings. This being so, Dr. Marenseller is more than questionable whether it would be wise to cut into pieces a sponge which, even though it has more quickly reached the same size and shape as the collective cuttings, and attention might be directed to the production of properly rounded though small, sponges from ill-shaped and even worthless ones. Possibly, also, the production of individuals of larger size and better form is effected, which, according to Carolini's experience and in Buccich's opinion, should present no difficulty.

#### BRITISH MUSEUM PRINTED CATALOGUE OF PRINTED BOOKS.

Another important step has been taken by the British Museum in the gigantic task of its voluminous MS. catalogue into a printed one. The catalogue already takes up more room in the Reading Room than can well be spared, and it is calculated that all the MS. entries are superseded by printed volumes will be reduced in number to about one-third of what they are at present. Some of the volumes now congested with entries, and it has therefore been decided to print these crowded entries in instalments. In order to carry this decision into effect, the first portion of the letter B has been printed in a folio form of 101 pages. The first volume follows:—

"B. 1. A. The Lord's-day, the Sabbath & the Digested dialogues between two D. and B. &c., 1436 fto. 4865. b."

The last entry is—

"B. y. 3. D. F. Florida, poema tragica in verso [in verse] Por D. F. B. y S. Valencia 1542, f. 1 (37)."

It is not intended to continue the printed catalogue in this particular order, but to deal first with those parts of the catalogue that require re-arrangement on account of the crowded nature of the MS. entries. It is

able that the letter B will be completed at the time.

printing of the old slips will not effect the progress of the catalogue of modern books and new ones which will be continued independently.

## MANUFACTURE OF MATTING IN CHINA.

United States Consul at Canton reports that the manufacture of matting is extensively carried on in especially towards the south, where it is one of the most important industries engaged in. Enormous quantities of matting are made both for export and for home use, much being used as sails on the sailing craft, as it is much cheaper, if not more so, than the ordinary canvas or sailcloth. It is used as coverings for boxes and packages in which sugar, cassia, &c., are exported; also in making bags, it being a very convenient mode of handling, especially when broken up into small pieces by constant stamping or "chopping" of the dollars, the custom in China. The plant from which the grass, &c., so extensively used in China, is obtained, is called "aquatic grass," also as "rush." It is cultivated in the Shuihing department on the West River, seventy-five miles in the interior from Canton. It grows in the same way as rice, in fields flooded with water. It requires very little care in its cultivation; it propagates itself by shoots from the root, and to a height of from six to eight feet. It is brought to market in bundles of about twelve inches in length, and if of proper length and good quality, it is worth about 10d. per bundle, each bundle being not to make four bed mats, or six such as are used for making sails. The district of Tung Kuan produces large quantities of this grass, but of a species most entirely in the manufacture of floor matting. It is said to grow better in the vicinity of salt water, the water flooding it is somewhat brackish. It is harvested usually in the month of June from slips. The slips are allowed to grow for about two months, then they are replanted in rows. The soil being usually manured with bean cake, it requires nearly two months to mature, when it is cut, the shoots or slips are split in two with a knife, and, when parried in the sun, packed in bundles, and manured into matting at the city of Tung Kuan, or sent to Canton, where there are several extensive factories. When brought to the factory, the grass is fully sorted, it is then made into bundles of two or three inches in diameter, and placed in large earthen jars, holding about ten gallons of water; it is allowed to remain thus in soak for three days, when it is taken out and dried in the sun for a day. If it is dyed the ordinary red colour, which has been for some time in vogue, it is placed in jars containing red dye, made by soaking red sapan wood chips in water.

It remains in these jars for five days, then dried in the sun, afterwards again immersed in the dye for three days, when it is usually ready for use. It is only used for the past two or three years that other colours, such as green, yellow, and blue, have been used to any extent. The solution for colouring yellow is produced from the seeds and flowers of a plant common to China, the "hui fa." A yellow colouring matter is made by boiling, for several hours, twenty pounds of *Sophora Japonica* in one hundred gallons of water, and adding, when cooled, one pound of alum to each ten gallons of the solution. The green and blue are produced from the twigs and leaves of the "lamyip" or blue plant, which grows in abundance near Canton. To the solution thus produced a quantity of chemical dye is now usually added. When these colours, the straw is soaked in water for three days, and then immersed in the colouring matter for a few hours only, the solution being hot. Consul

Lincoln states that in a recent visit to one of the largest manufactories, he found fifty looms being worked, eight of which were large, and forty-two small. The large ones are exactly the same as the ordinary silk loom, and are used in making the very wide, and also the damask or carpet patterns. Three men are required to work each of the large looms, their wages being from 1s. 3d. to 1s. 8d. a day. Eight yards of matting from each loom is considered an average result of a day's work. The small looms are rude and simple, each being worked by two small boys, who are paid from 7d. to 10d. per day each, and who daily weave five yards of the most perfect matting of the more ordinary patterns. The loom is composed of two uprights, driven into the ground, about five feet apart, and about four feet in height, two cross-bars fit into sockets in the uprights, one at the top, the other about eight inches from the ground. The warps, which are strings of Chinese hemp, two yards and a-half in length, are then passed over the upper, and round beneath the lower cross-bar, through the holes in the weaving bar, and, being drawn taut, are fastened by both ends to a long, thin piece of bamboo, placed parallel with, and just below the lower cross-bar. The weaving bar, and the most important part of the loom, consists of a piece of wood, varying in length according to the width of the matting required, and about two inches square; through this, small holes are pierced at different intervals, into which the warps are passed; the bar can thus be worked up and down in the warps by means of handles near the extremities—these holes vary in distance from each other according to the pattern desired—alternately on top and bottom. The holes are enlarged, or formed into slots, converging at the centre of the stick. When the warps have been thus arranged, and bundles of different coloured straw, sufficiently damp, deposited near the loom, one of the boys raises the weaving bar to the top of the warps, tipping it forward, the slits in the bar allowing the alternate warps to remain perpendicular, the holes carrying the others forward, thus separating them sufficiently to admit of a single straw being passed between them. This is done by a long flat piece of bamboo, a notch being cut near the end, into which one end of the straw is placed, and then used as a shuttle. When the bamboo is withdrawn, the weaving bar descends, carrying the straw to the bottom; the bar is then raised again and tipped down, thus carrying the warps backward which had just before been passed forward, the work of the shuttle being repeated. As the weaving bar presses the straw down, the weaver gives the ends of the straw a half-turn round the outside warps, the operation being repeated until the warps are full, the edges trimmed, the warps untied, the matting now two yards in length removed, and a new set of warps put on. The matting thus woven is then dried in the sun, and over a slow fire. The shrinkage consequent on this drying is nearly four yards in forty. When dried it is stretched on a frame and worked down tight by hand, then sent to the packing-house, where men are engaged in fastening the two yards lengths together, it requiring twenty lengths to make the ordinary roll. The fastening together is done by taking the projecting ends of the warps of one piece, and by means of a large bamboo needle, passing them backward and forwards through the reeds of another piece, in fact, sewing them together; each roll of forty yards is then carefully covered with a coarse, plain, straw mat, marked and numbered ready for shipment.

## COOLACHAN OIL A SUBSTITUTE FOR COD LIVER OIL.

Under the above name a new medicinal oil has lately been introduced to English commerce. It is said to so closely resemble cod liver oil, both in appearance and

## OF THE SOCIETY OF ARTS.

No. 1,489. Vol. XXIX.

FRIDAY, JUNE 3, 1881.

*Notes for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## CANTOR LECTURES.

d and concluding lecture of the fifth "Colour Blindness, and its Influences on Industries," was delivered by R. Carter, F.R.C.S., on Monday, 30th ult. was drawn to the industries chiefly colour blindness, and the dangers and consequences consequent on the defect in the engine-drivers, pilots, artists, letter pressers, painters, &c. The lecturer alluded at legislation in the United States, and the urgent need for legislation in this

IRMAN (Dr. Mann, F.R.C.S.), in moving vote of thanks to Mr. Brudenell Carter (interesting and instructive course of new attention to the curious fact that important defect of the human eye—one with the most serious dangers—should have been discovered within a comparatively short time. He thought, in listening to these remarks of Helmholtz, that among the most remarkable scientific discoveries of the present time, which related to the domain of medicine, were, perhaps, the most remarkable. These remarks will be printed in the *Journal* in the autumn recess.

## MEMORIAL TABLETS.

In the past month new tablets have been erected in six houses to commemorate the residences of the following celebrated men:—  
1.—36, Castle-street, Oxford-street.  
2.—30, Leicester-square.  
3.—has been rebuilt for Archbishop Tenison's

4.—35, St. Martin's-street.  
5.—16, Buckingham-street, Strand.  
6.—14, Savile-row.  
7.—5, Arlington-street.

The following is a list of tablets previously erected by the Society of Arts:—

Burke—37, Gerrard-street, Soho.  
Byron—16, Holles-street, Cavendish-square.  
Canning—37, Conduit-street.  
Dryden—43, Gerrard-street.  
Faraday—2, Blandford-street, Portman-square.  
Flaxman—7, Buckingham-street, Fitzroy-square.  
Franklin—7, Craven-street.  
Garriek—6, Adelphi-terrace.  
Handel—25, Brook-street.  
Johnson—17, Gough-square, Fleet-street.  
Napoleon III.—3a, King-street, St. James's.  
Nelson—147, New Bond-street.  
Reynolds—47, Leicester-square.  
Mrs. Siddons—27, Upper Baker-street.

## DOMESTIC ECONOMY CONGRESS.

Her Royal Highness the Princess Christian, President of the Congress, took the chair at the meeting of the Ladies' General Committee, held on Wednesday, 1st inst., in the Great Room of the Society of Arts. The following ladies attended:—The Countess of Airlie, the Countess Spencer, Lady Arthur Russell, Viscountess Strangford, Lady Marion Alford, Lady Jane Stewart, Lady Charlotte Schreiber, Lady Reay, Dowager Lady Stanley of Alderley, Lady Knightley, Lady Cole, Lady Clive Bayley, Lady Hogg, Mrs. Bartley, Mrs. Burke, Mrs. Russell Carew, Mrs. Charles, Mrs. Cotton, Mrs. Dacre Craven, Mrs. Cromwell, Mrs. Fowke, Mrs. Grenfell, Mrs. Holland, Mrs. Lecky, Mrs. Mann, Mrs. Fenwick Miller, Mrs. Peploe, Mrs. Price, Mrs. Priestley, Mrs. Seeley, Mrs. Stansfeld, Mrs. Tubbs, Mrs. Webster, Miss Rose Adams, Miss Andrews, Miss E. Barnett, Miss Cole, Miss Gurney, Miss Hamonds, Miss M. Hooper, Miss Fay Lankester, Miss H. Martin, and Miss Stanley. Sir Henry Cole, Lord Alfred S. Churchill, and the Rev. Newton Price, members of the Executive Committee, were also present.

## PRACTICAL EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

The next Examination in London will be held by Dr. Hullah, the Society's Examiner, at the House of the Society of Arts, 18, John-street, Adelphi, W.C., during the week commencing on the 4th July, 1881.

The examination of each candidate will be private; no one but the Examiner and the accompanist being present, unless it be a member of the Society of Arts' Committee.

No list of Candidates will be published.

Full particulars can be obtained on application to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

## FOREIGN AND COLONIAL SECTION.

Tuesday, May 31, 1881; Sir HARRY PARKES, K.C.B., H.B.M.'s Minister in Japan, in the chair.

The Chairman, in calling upon the Secretary of the Section to read the paper, said he regretted that Mr. Gubbins was not present to read the paper, being obliged to absent himself through ill-health—the same cause which had brought him home to England for medical aid. The position of this little kingdom in the Pacific was very curious, on account not only of its antiquity and of its advances in civilisation, but also of the very peaceable and excellent disposition of its inhabitants. We, in England, had little acquaintance with these islands, as they lay rather out of the ordinary routes of commerce, but Englishmen had landed there occasionally for more than sixty years, and whenever a foreigner had done this, he had been struck by the cordial reception he met with. About four years ago he (the Chairman) had occasion to visit the islands, and one of the first things he was shown was the grave of a seaman belonging to his Majesty's ship *Alceste*, who was buried there in 1816. The tomb was kept up with great care, and the inscription was almost as legible as the day it was cut. Of course he expressed his gratitude for the care which had been bestowed on the grave of a fellow countryman. Although this little State had had its own autonomy for many centuries, it had lately been the subject of a political question between the empires of China and Japan, to both of which it had been accustomed to pay tribute. This could hardly be expected to continue indefinitely, and Japan had lately made special claims, and annexed the whole islands, so that Loochoo had, in fact, now ceased to exist as an independent principality.

The paper read was—

## NOTES REGARDING THE PRINCIPALITY OF LOOCHOO.

By John A. Gubbins, of the Consular Service.

A common mistake made by foreigners in China and Japan is to suppose that the principality of Loochoo—which, for several centuries, has existed as a tributary State, owing allegiance both to China and Japan, but at the same time governed by her own laws, and having her own peculiar manners and customs—includes the whole of those islands known to navigators as the Loochoo group. The northern islands of this group, however, of which the principal are Oho-sima, Yarusu-sima, and Kikai-sima, have been Japanese possessions for nearly three hundred years, and at a comparatively recent date another small island was added to the list.

Loochoo proper consists of the large island of Okinawa-sima, and nine outlying groups. There are besides smaller islands, more or less distant, which are too numerous to mention in detail.

According to statistics obtained on the spot, the total population of Loochoo in 1875 was 165,930, divided as follows:—Main island—Shizoku, 29,633 men; 29,722 women. Heimin, 28,980

men; 28,981 women; total, 117,310 islands of which the Miyako group composed half, 62,495, the proportion of women slightly in excess of the men.

The population of the main island is equally distributed, more than half of the inhabitants being included in the which are also distinguished from the country by the fact that the population is composed almost entirely of Shizoku. The Okinawa has three large geographical districts, which are subdivided into thirty-five districts, that are again divided into villages.

## CLASS DISTINCTIONS AND NOBILITY.

The people of Loochoo may be roughly divided into two classes—Shizoku and Heimin—a distinction borrowed from Japan. The king, of course, the head of the State. Next to him rank come.—1. Nobles of the first rank and first grade. This class comprises the uncles, brothers, and sons of the king, who have the title of *Shizoku*. 2. Nobles of the first rank and second grade. This class comprises all the other relations of the king, who have the title of *Andzu*. The nobility then follow in the order given—Second rank, first and second grades, (the "Sandzukwan," or Thrukia Oyak) virtue of their position take rank with the Third rank, first grade to sixth rank, first grade, Paikin. Seventh rank, first grade, S Paikin. Seventh rank, second grade, C Paikin. Eighth rank, first grade, S Paikin. Eighth rank, second grade, Wakasatonosh rank, first grade, Chikudon. Ninth rank, first grade, Chikudon Zashiki. No rank of Zashiki. These titles are quite independent of official designations; they are not hereditary, and are conferred on individuals in recognition of services rendered to the State.

## GOVERNMENT DEPARTMENTS AND OFFICIALS.

The King of Loochoo is nominally at the head of the Government, but his share in the administration is very small. All affairs are carried on by officials chosen from among the nobility, at the head of whom is the Prime Minister, who is selected from the nobles of the blood, or, failing such, from the relatives. It may, indeed, be said that the King presides over the Council of State, Sandzukwan divide the heaviest responsibilities of Government between them.

Some idea of the system of Government may be gathered from the following list of public departments and the officials attached to them.

Hiôjô-shô, or Council of State, which has the superintendence of all important business alone has power to decide matters of State. This is attached to the Prime Minister Sandzukwan (who are not chosen by the King but by the general vote of the leading nobles). The rest of the staff is made up of the Head Secretary and six Under Secretaries of the Sandzukwan has charge of the Department, and the control of matters connected with mountains; another has charge

\* This term is evidently taken from an old land name, called Magiri.

epartment, and the control of matters in rivers. These two serve alternately at a time. The third has charge of office, and the control of districts and

sho, or Home and Finance Department sub-departments, viz. (1) Finance control over receipts and expenditure in the productions of various districts (2.) Salary Office; (3.) Office where agency, such as landslips, inundations, with.

Sho, or Foreign Office. The duties are—(1.) Conduct of relations with us; (2.) Distribution of rewards and

Judicial Department, with a staff of irato-to-soba, and two Gimi. Sho—Department of Ceremonies; Kin-jiu-ho, household; Kei-dzu-za, or Herald's Office; Jisha-za, or Registrar's Office; Jisha-za, Religion; Yobutsu-za, or Chinese Department; Tachi-ho, or Board of Yamabugio-sho, or Department of Forests; Fushinbugio-sho, or Public Treasury; Shi-jose-za, Office for Control of Tribute, and other business connected

the principal Government Department would be too tedious to go through the of minor offices. The most trivial of these have separate offices for their con- others are—the O-dai-dokoro, or the Rionza, or office for super- preparation of food for banquets of Chinese delegates and other foreign in Loochoo for the time being; the Government stables; the So-yo- Board for supervision of the manners of the people; and the Kawara-bugio- for controlling the manufacture of roofs of houses.

duty of collecting the revenue, and of receipts and expenditure, are six or seven different departments. above-mentioned offices, each district, or local office, and to each of these one Jito, or lord of the manor, one Shiuri-Yako, one Osabakuri, one ri, and several Sabakuri, the number of fixed. The first three are appointed and are not natives of the district. offices are filled by local men. The administer the islands of Miyako and are—one Zaiban, or Governor, three three to five Oyako, and several sub-als.

In the case of the districts, the officers of Oyako are local men. There are also called Yenin, detached for foreign an.

Since there has been a Loochooan since the conquest of Loochoo by 1610, and Oyakata and other leading reside in it. Since 1868, however, the have been called the Kura-Yashiki, and the Home and Finance Department have a term of one year at a time, their ng to superintend the purchase of a Han. Although in the time when

tribute was paid to China, a resident interpreter was attached to the Loochooan factory at Foochow, there was never a regular foreign service similar to that adopted in the case of Japan.

The laws of Loochoo include, in addition to a Civil and Penal Code, a complete set of regulations concerning the distribution of rewards. One or two instances will suffice to illustrate the character of these rules:—

*Rewards* (including increase of rank, official appointments, and presents of goods) are given to persons who promote the interests of agriculture in various ways, which are detailed; who have made themselves conspicuous by deeds of charity and benevolence; who give assistance in cases of famine and shipwreck; who attain the age of 100 years; to officials who lessen official expenditure; who improve the Government finances by inaugurating reforms of various kinds; to women who show great respect to their husband's parents; and to widows who remain single.

With regard to the Civil Code I have been unable to gain any information.

The Penal Code of Loochoo is based on the laws of China, and the ancient laws of Satsuma. It is remarkable for its simplicity and severity, and the influence of Confucianism may be clearly traced. I understand, however, that the penalties laid down were by no means strictly enforced. By order of the Japanese Government the Loochooan criminal code was lately abolished, and Japanese criminal law has taken its place. Still, in spite of the fact that these laws have ceased to exist, the following short notice of them may not be without interest.

Offences in respect to parents, ancestors and relations, ranging from murder down to simple assault, were punished with crucifixion, decapitation, or banishment, according to the gravity of the crime. The murder of a husband by his wife, was punished with crucifixion. Murder in other cases, forging the Government seals, opening or rifling graves, burglary, accompanied by manslaughter, and other personal violence, with decapitation. Bribery, libel, the profession of Christianity or other religion not recognised in Loochoo, adultery, theft of official money, entering the castle without permission, and gambling (second offence), were punished by banishment—in some cases to uninhabited islands.

Violence offered to people by persons under the influence of drink was punished—In the case of Shizoku, by confinement in temple buildings; in the case of Heimin, by flogging and imprisonment; in the case of officials, by dismissal. Taking a man's wife and children in pledge for money lent was a punishable offence, but did not come under the head of grave crimes. Those also who charged a higher rate of interest on money lent than 20 per cent. per annum were punished. Two things are brought out very clearly by these laws—namely the subordination of a wife to her husband, and of the Heimin to the Shizoku.

#### REVENUE AND EXPENDITURE.

On this subject I obtained the following information from the Home Office Secretary, resident at Nafwa. The yearly assessment of cultivated lands in Loochoo, is fixed at 94,233 koku of rice, of which 75,134 koku are contributed by the

main islands, and of balance by the adjacent islands in the jurisdiction of the Han.

The taxes in Loochoo may be divided into two kinds—*seizei*, or regular taxes, and *zatsuzei*, or miscellaneous taxes. The *seizei*, or regular taxes, form the revenue of the Government, and consist of rice, 21,580 koku; sugar, 2,048,239 koku (probably catties); other cereals, 5,379 koku; millet, 4,877 koku; cash, 2,705,768 kwan = yen 48,115<sup>2</sup>/<sub>3</sub>. As against this, the Government expenditure is as follows:—Tribute paid to Japan, 11,122 koku of rice. Office expenditure—Rice, 5,171 koku; other cereals, 4,066 koku; cash, 31,187,720 kwan = yen 623,754<sup>2</sup>/<sub>3</sub>. Expenditure of King—Rice, 1,046; incomes of Han retainers—Rice, 2,867 koku. Officials' salaries—Rice, 3,113 koku; other cereals, 2,027; cash, 285,563 kwan = yen 5,711<sup>2</sup>/<sub>3</sub>. The miscellaneous taxes (*zatsuzei*) are local taxes paid by the people of the various villages and districts to the lords of the manor (*jito* and *wakijito*). With regard to these Mr. Kinashi, the resident secretary of the Home Office, informed me that in spite of repeated efforts, he had found it impossible to obtain reliable statistics on the subject. These taxes, it appears, are not fixed, but vary in each village, according to the quality of the soil, and the number of inhabitants, and the amount to be collected is left very much to the discretion of the local lord of the manor. Charcoal and firewood are included under the head of this indirect taxation, and I ascertained that it is in the power of the *jito* to levy the taxes due to him in any form which suits him. Thus, if he wishes to lay in a stock of fuel for the winter, he may demand to be supplied with charcoal and firewood to the amount necessary for his use, and, instead of paying for it at the time, he may subtract the value of the supplies furnished from other taxes due to him. He may also employ labour to any extent which he may think fit, the wages of the people employed serving as a set-off against the taxes to be collected from them. It is obvious that under such a system as this the greatest injustice can be committed. To a man who earns his hiring from day to day, it is the greatest hardship to be taken from his daily employment, and be compelled to do work, the payment of which is deferred to an indefinite period. In such a position the labourer becomes little better than a slave.

#### PRODUCTIONS OF LOOCHOO.

According to a table of statistics (which is compiled from native sources), kindly furnished to me by the Japanese Home Office authorities at Nafwa, the value of the total exports from Loochoo to Japan during the year amounts to\* yen 241,300, as against imports to the extent of yen 121,800, leaving a balance in favour of the islands of yen 119,500.

**Imports.**—The imports from Kagoshima, which serves as the port of connection between Japan and Loochoo, are:—

\* In the case of exports, the exchange between Loochooan and Japanese currency is taken at 50 kwan to the yen, this being the rate ruling at the Port of Nafwa. In the case of imports, the Kagoshima rate of exchange, 32 kwan to the yen, has been adopted. If the same rate be taken for the imports as for the exports, the total value of the former will reach yen 140,000, thus greatly reducing the balance in favour of the islands.

	Yen.
Rice .....	30,000
Beans .....	3,400
Rapeseed Oil .....	5,000
Tea .....	1,200
Lacquer .....	1,200
Tobacco .....	4,000
Vermicelli .....	2,500
Raw cotton .....	8,400
Thread (cotton) .....	26,600
Miscellaneous, including dried fish, saki, seaweed, hair-oil, timber, iron, iron-ware, hardware, and foreign goods (about) .....	16,900

Total ..... Yen 121,800

The above figures do not include some minor items, the returns for which have not been obtained; and in the case of each item, it must be borne in mind that the figures represent only the approximate annual amount.

**Exports** (principally to Kagoshima).—Some figures, of course, as the chief item, the average yearly export of this article being 6,500,000 catties, representing an approximate value of yen 162,500, or more than two-thirds of the total value of the exports.

Statistics are wanting in the case of the other articles, but they may be roughly estimated as follows:—

	Yen.
Cotton cloth .....	28,000
Hempen cloth .....	12,500
Other cloth .....	7,200
Tenmugi (silk fabric) .....	2,800
Yellow dye (ukon) .....	900
Loochooan saké (awamori) .....	2,500
Medicinal drugs .....	2,700
Salted pork .....	2,300
Umbrellas .....	950
Rope .....	650
Miscellaneous .....	18,300
	78,800
Add sugar .....	162,500

Total ..... Yen 241,300

The exports above mentioned naturally afford an indication of the principal productions of the country. But there are other productions, which for obvious reasons, do not figure in the list of exported goods. Under this head come

**Potatoes.**—Which may be regarded as the staple food of the islands.

**Rice.**—Which gives two crops, one grown in the spring and one in the autumn, yielding some 32,000 koku.

**Indigo.**—Used everywhere as a dye, and grown by individuals for private use.

**Peas and Beans.**—Both Japanese and foreign varieties, the latter having been introduced within the last 60 years. Capt. Hall, in his "Voyné and Journal," speaks of having given the seeds of various English vegetables to the Loochooans, and adds that they were instructed how to grow them. The date of his visit, in H.E. Lyra, to the Loochooans—1816—corresponds with the date of their introduction as mentioned to me by the natives.

**Millet.**—

**Palms.**—Which are grown extensively under the superintendence of the Government, in order to

resource in times of famine, the heart of ng eaten.

Horses, bullocks, pigs, and goats). er is obliged to keep three or four pigs the sake of the manure which is thus ould he fail to do so, a money payment

This production, to the growth of which s owe whatever commercial importance s, is stated to have been introduced into om China in the year A.D. 1623. At oms by far the most important product ds. I was unable to procure statistics ge yield of the year, although, judging mber of Government offices which are n the cultivation of sugar, and in its s a portion of the revenue, the most ormation in this respect ought to be

In former years the trade in sugar oochoos was in the hands of the Satsuma it is doubtless in part owing to the f this lucrative monopoly that Han h a flourishing condition. The sugar conveyed to Kagoshima, from the a large proportion—that coming from and Yarabusima—being actually the the Han), and thence it was sent by ink to Osaka, where it was sold in y the Satsuma agents at the Yashibi of the highest bidders by written tender. nts who purchased it then retailed it to lers, and it was in this way gradually to different parts of the country. It is hat the value of the sugar which used ough the hands of the Satsuma autho- ot less than yen 500,000. This estimate, idging by the present export of sugar oo proper, seems to be rather large. Of since the abolition of the Han, the sugar ough by private merchants and trading at Kagoshima and Osaka, and no r the trade is exercised by the Govern-

r plantations are owned by private land- proprietorship not being restricted to Each proprietor has his own sugar niently near to the plantations. These very primitive construction. Imagine pace some 30 feet in diameter. In the is are three cylindrical rollers arranged de by side. The centre roller is higher o others, and is turned by means of a astened to the top of the roller, and to a pony or bullock, who moves along a h on the outer edge of the enclosure. f simple cogs, made so as to fit one into e centre roller turns the two others.

fed by two men, who sit one on each ch cane is crushed twice, being passed tween the centre and the right hand passed back again between the centre he roller on the left. The juice, as it l, falls into a trough underneath the ough this it runs into a tub, which, s emptied into the ovens close by.

s are round, open at the top, and built Each is protected from rain and wind ed roof, which also affords shelter to attend to the fire. The process of

boiling the sugar is simple enough. Before light- ing the furnace below, three shallow iron pans are arranged in the oven, in the form of a trefoil, and the spaces between them and round the side of the oven are built up with a mixture of clay and straw. The liquid sugar is then poured into the pans, and, the furnace being lighted, is allowed to boil five or six hours. During this operation, the burnt ash of a stone collected on the sea-shore, is mixed with it in definite proportions. When the sugar is sufficiently boiled, the pans are removed, and placed in the open air. Here the sugar is stirred until it becomes cool, and it is then poured into tubs, where it forms a solid cake. Each tub holds about 120 cattles. Sugar is conveyed by coolies from the plantations to Nafwa, whence it is ex- ported to Japan. The boiling season is during the cold weather, from November to February.

#### FOREIGN INTERCOURSE.—RELATIONS OF LOOCHOO WITH JAPAN, CHINA, AND OTHER FOREIGN POWERS.

The ancient history of Loochoo is enveloped in mystery, and its earliest historical traditions bear a resemblance to those of its larger neighbour, Japan. Considering that the first native history of Loochoo, the "Chinzan Sekan," was not compiled till the year A.D. 1650, the legendary character of these traditions is no matter for surprise; but the claim upon our credence passes all reasonable bounds.

We are asked to believe that the dynasty, of which the first ruler was a mythical personage known to posterity as Tensonji, existed for a period of 17,800 years, ending in A.D. 1190. In the latter year, a new dynasty was founded, according to Japanese accounts—which the Loochooans are far from accepting as fact—by a Loochooan of Japanese descent, under the following circumstances:—

In the spring of the year 1165, Minamoto Tamétomo, who had been living for some years in retirement in Oho-sima, whither he had been banished after the defeat of his family by the rival house of Taira, took ship and sailed west- ward in search of adventure. After a voyage of long duration, he arrived at the harbour of Unten, in the extreme north of the main island, Okinawa. He was received kindly by the Loochooans, and stayed on the island for seven or eight years, during which he gained the friendship of one of the local potentates, Ufuzato no Andzu, the lord of the district of Ufuzato, and married his daughter. Two years after the marriage his wife bore him a son, who, in 1190, succeeded to the Loochooan throne, taking the name of Shunten. The reasons given for his succession are briefly as follows:—The twenty-fifth of the old line of Loochooan kings was a man of feeble character, who allowed the administration to fall into a state of complete disorder. His misrule led to a revolution, in which he was deposed and killed by a powerful noble, named Rin, who seized the throne. But the latter was in his turn deposed by the son of Tamétomo, who, left in Loochoo at a child of six years of age, when he returned to Japan, gave evidence of so much ability as he grew up that, at the early age of 15, he was made lord of the district of Urasoyé. He was only 22 years of age when he ascended the Loochooan throne. Tamétomo is said to have instructed his son in the Japanese

syllabaries, and the latter is credited with their adoption in Loochoo.

There are several Japanese works (also one, if not more, Chinese books) which contain accounts of Loochoo, and in which mention is made of the intercourse which has taken place in past centuries between Loochoo and foreign countries. From a summary of extracts from these works, which are given in the "Okirawa Shi" (a recent work on Loochoo, written by a Japanese), it appears that the Japanese claim to have received tribute from Loochoo as early as the year A.D. 616, in the course of which several Loochooans arrived in Japan. Tribute was not then paid regularly, and consisted of articles of little value, principally palm-wood. The fragment of this tribute—if the occasional presents which marked the existence of friendly relations between the two countries may be called by that name—continued up to the year, A.D. 754, when the Empress Koken was on the Japanese throne. From that time till the year A.D. 1610, intercourse between the two countries appears to have ceased. It may be that the Japanese Government advanced claims to suzerainty which the Loochooans declined to admit. However, in the latter year, Loochoo was invaded and conquered by the Satsuma clan. The first attempt made by the Satsuma force to land at Nafwa was repulsed, and the invading force consequently landed at Unten, the northern harbour. The campaign is said to have lasted only 40 days.

The tribute then assumed a definite shape, the amount payable yearly to the Satsuma Treasury being between seven and eight thousand koku of rice. From this period also dates the custom of sending a congratulatory mission to Yedo on the accession of a new Shōgun to the Shōgunate. On these occasions, presents of silk, lacquer-ware, and Loochooan saké were made, and return presents were received by the members of the mission. In 1727, the tribute was increased to about 12,000 koku, which amount was collected annually by the Satsuma Han, until the year 1871, when the Han were abolished, and Ken established in their stead. Loochoo was then made a Han, and placed under the control of the Kagoshima Ken. The tribute continued to be levied on the same scale, with this difference, that instead of forming part of the revenue of the former—Satsuma Han—it was paid into the Ken exchequer, from which it found its way to the Finance Department at Tôkiô. In the following year, 1872, a mission arrived in Yedo to congratulate the Emperor on his assuming the direct control of the Government. Presents were exchanged between the two countries, and congratulatory epistles were presented to the Emperor and Empress of Japan by the King of Loochoo. In reply the latter received an Imperial message. This opened by stating that the climate and language of Loochoo were similar to those of Japan, and that as the King Shōtai held a high position, a fitting title was assigned to him, namely, that of King of the Loochoo Han, with rank amongst the nobility of Japan, and that in return he was expected to acquit himself well of his grave responsibilities, and render loyal assistance to the Crown. In the same year a further decree was issued, to the effect that the treaties concluded between Loochoo and the three

foreign Powers of America, France, and Italy were to be considered henceforth as treaties with the Imperial Government, and that Loochoo was to be under the control of the Imperial Office, four Foreign Office officials were stationed as residents in that country. A Japanese was also assigned to them in Ida-machi, and the King was made an official of the first rank. The Loochooan Embassy then returned with Japanese Foreign Office officials to their country.

In 1873, Yonabara Oyakata, one of the Saiban, accompanied by a suite of five sub-officials and twenty attendants, was sent as Resident Commissioner, and established himself at Loochooan Yashiki in Tôkiô.

During the first three years of his residence in the capital, it was customary for him to visit the Emperor twice every year at the festival of the Tenchō Setsu, and at the New Year. Twenty pieces of silk cloth and thirty pieces of cotton cloth were presented. But, in 1876, this custom was abolished by the Japanese Government.

In the autumn of 1874, the Loochooan was placed under the Home-office, and at present the secretary of the Home-office resides in Naha, and conducts negotiations between the two Governments. The amount of tribute was also reduced to 400 koku.

*China.*—If certain ancient records may be taken as correct, the Chinese appear to have made attempts in centuries past to open up intercourse with Loochoo. As far back as the year 221 B.C. a Chinese official sailed from the port of Fusan in search of adventures, and was the first to set foot in Loochoo. Being unable to converse with the natives of the island, he almost immediately, abandoning one of his crew, who was taken prisoner. The next attempt at reception would seem to have reached the Chinese Government, for, two years later, another official visited Loochoo and declared that the Loochooans should tender their submission to China. This, however, they refused to do accordingly, in the course of the next two years a third Chinese mission arrived, bringing with it is stated, interpreters from Koron.\* The Loochooans still proving obdurate, hostilities were commenced by the Chinese, who burnt a number of villages and carried off a number of prisoners.

The next we hear of relations between the two countries is more than 600 years after, when some Chinese who landed at Naha were driven away by the natives with the loss of many men. For this outrage reprisals were made in the same year, and in the raid which followed the Chinese undertook more than a hundred Loochooans were seized and brought back as tribute to China. It was not till nearly a century later that the payment of tribute by Loochoo to China commenced. In 1314, a civil war broke out in Loochoo, which had the effect of dividing the country into three separate States, each with its own king; and some sixty years after, in 1372, the Ming dynasty being in possession of the Chinese throne, a Chinese mission arrived at Loochoo, and yielding to the pressure of

\* In Chinese, Kivenham, meaning "fabulous region."

of the Loochooan State—Chiuzan—nger brother with a letter to the king. In this, he tendered his submission to the Chinese Emperor, and accepted his status of a vassal State. The kings of the States shortly afterwards followed thus given to them, and all three of them in their titles as kings of the three uzan, Chiuzan, and Nanzan.\*

In 1428, Loochoo became united once under the rule of the king of the central island. The following year the number of ships from Loochoo to China was fixed by the Government at two every alternate years, was settled that the complement of ships should not exceed 160 persons. A Loochooan mission was also established at Foochow, and anshikwan (or residence of the Han

the number of the Loochooan mission, the crews of the two vessels, was in 160 persons; and five more were added in 1600. Officials who had permission to go to Peking to pay tribute to Peking. Later on—the number was uncertain—the Chinese enacted the law that the tribute should be sent once every year; but, in 1857, in a memorial on the subject from the Loochoo, the Chinese Government issued the following effect:—That the tribute should be sent once every two years; that the number of ships, all told, should not exceed 150, that of these only the Ambassador and his staff, with a following of 15 persons, should be allowed to visit Peking.

The Loochooan Government petitioned to be allowed to send another vessel, the "Kōsen," in company with the tribute ship, the object being evidently to secure facilities for trade. It is clear that the Loochoos at this time took advantage of the facilities established with China by means of ships to carry on trade, for we read in the memorial that the Chinese Government was asking to be allowed to increase the number of the mission, and to conduct their trade.

These requests were granted. The number of the mission was increased to 200 persons, and duties on imports and exports were abolished. From this date till the year 1874, no change was made in the tribute to that of late years it became for the two tribute junks and the ships as we may call the additional ship (no distinction) to go in alternate years, the number of officials who visited Peking was six, with a suite of six attendants. In 1874, however, the Japanese Government issued an edict forbidding the payment of tribute to China.

*Notes.*—Special missions were always sent whenever a new Chinese Emperor, or Loochooan King, ascended the throne. The visit to Peking was conducted with display, twice the usual number of ships were allowed to accompany the tribute to court.

On ordinary occasions the number of the mission was 20, but the attendants were numerous, and these, together with the crews of the two tribute ships, brought the total up to two hundred persons. The *sekkōsen* carried eighty people.

Fourteen officials, including the Saifu and Head Interpreter, remained in Foochow (one official, the Resident Assistant Interpreter, being appointed to reside in that town for a term of two years, being replaced at the expiration of that period). The Ambassador (Taifu), Peking Interpreter, Peking Chief Secretary (Yoriki and Gisha), in all six, with six attendants, proceeded with the tribute to Peking.

The tribute paid on ordinary occasions consisted of—Sulphur, 12,600 catties; copper, 3,000 catties; tin, 1,000 catties.

The tribute paid on the accession of a king in Loochoo was as follows:—For the Chinese Emperor—2 golden tevru (ornaments), 1 suit of armour, 2 pair of gold-mounted swords, 2 pair of silver-mounted swords, 20 swords, 10 spears, 10 halberds (*naginata*), 1 suit of horse trappings, 2 gold-mounted screens, 100 gold-mounted fans, 200 silver-mounted fans, 200 ordinary fans, 200 packages of raw cotton, 300 pieces of silk, 100 pieces of cotton, 500 catties of copper, 500 catties of tin.

The tribute paid on the accession to the throne of a Chinese Emperor was as follows:—For the Emperor—1 pair of golden vases, 1 pair of silver vases, 4 swords (gold-mounted), 4 swords (silver-mounted), 200 pieces of silk, 2 pair of gold-worked screens, 200 fans, 5,000 pieces of paper for screens and walls, worked in fancy patterns, 500 catties of copper, 500 catties of tin. For the Empress—1 pair of gold boxes, 1 pair of silver boxes, 80 pieces of silk, 80 fans. For the ex-emperor or deceased emperor—100 *riōs*, in money. In return for this tribute, presents were given to the King of Loochoo, and to nearly every member of the mission, even down to the common attendants.

#### OTHER FOREIGN INTERCOURSE.

The intercourse between Loochoo and other Foreign Powers has been very limited. In 1816, the islands were visited by H.M. ships *Alceste* and *Lyra*, and permission was received to bury on shore one of the sailors who had died during the stay of the vessels. Captain Hall, in his account of the Loochoos, speaks very highly of the kindness of the inhabitants, and states that although it was difficult at first to disarm the suspicions which the unexpected visit engendered, he ultimately succeeded in establishing the most friendly relations with the officials and people.

In the years 1844, 1846, and 1847, some French missionaries and an English doctor, were left on the main island by ships, the captains of which endeavoured to induce the Loochooans to trade with them, but without success, and in the ensuing ten years, other desultory visits were made by foreign vessels, in the course of which, several French missionaries were landed and left to reside, in some cases, for six or seven years. But these missionaries appear to have failed in their efforts to make converts, for, with the exception of one who died, all eventually left Loochoo.

In 1854, Commodore Perry, with an American squadron, visited Loochoo, and concluded a

\*AN-SAN.

ing the tribute junks to leave in the summer of the "sekkōsen" would not leave till the following

treaty on behalf of the United States with that country, and in the years 1856 and 1859, respectively, similar treaties were negotiated by France and Holland. It is stated that the negotiations in each case were watched by emissaries of the Satsuma Han, who attended all the interviews as spies, attired in Loochooan dress.

#### RELIGION.

Loochoo has no state religion, but Confucianism, Buddhism, and Shintoism exist side by side, like Confucianism, Buddhism, and Mohamedanism in China. Confucianism is of the oldest date, and is the religion, so to speak, of the Court and upper classes, while all three are equally professed by the lower portion of the population. Ancestor worship, and the respect due to seniors, which is its natural outcome, are, more than any established creed, the guiding principles of Loochooan life. The two Buddhist sects, which have old establishments in Loochoo, are the Zen and Hokkē. At Shiuri there are two or three temples, and the same at Nafwa. But, neither Buddhism nor Shintoism are regarded with much respect, and it is clear that they have no hold on the minds of the people. Both temples and shrines are of the rudest construction, offerings of devotees are conspicuous by their absence, and traces of persistent neglect are only too apparent everywhere. Of late years, a third sect of Buddhists has established itself in Nafwa, but owing to the determined opposition of the Government, the priests of this sect have not made much progress.

#### SCHOOLS.

There are 30 schools in Loochoo; 18 of these are in Shiuri, viz., one national school, for princes of the blood of Shizoku, from 18 or 19 years upwards; three Hira Gakki, or district schools, for sons of noble families and Shizoku, from 17 and 18 downwards; and 14 Mura Gakkō, for sons of Shizoku and Heimin alike, from six or seven years upwards.

The course of instruction in these schools includes the Chinese classics, and the Japanese syllabaries. The school in Kirunei Mura, however, is set apart for the teaching of Chinese, and is attended by those who wish to become Chinese interpreters besides the inhabitants of that town.

Correspondence by letter is conducted both in the Japanese and in the Chinese style; but the latter is mostly affected by the higher classes, who receive special instruction in the different branches of Chinese education.

Women receive no instruction in reading and writing.

#### WEIGHTS AND MEASURES.

The weights and measures used in Loochoo are based on those of Japan. The same terms are used both in square, lineal, cloth, and grain measure, and in calculating amounts of sugar; and with the exception of occasional differences such as dividing the "ei" into "go," "shaku" and "Sai"—a method which still prevails in Satsuma—the systems are the same.

#### CURRENCY.

There is no gold or silver in Loochoo, and the only currency consists of the copper cash coined

in Japan during the period of Kwany 1624-44).

Previous to this period, all commercial transactions were carried on according to the method of bartering one article for another, to remedy the inconvenience resulting from the want of proceeding, rice gradually became the medium by which values were estimated, and the relic of custom exists to this day. The hire of a boat fixed at so many "sho" of rice, according to the distance of the voyage. In 1694, the Loochoo petitioned the Satsuma Government to be allowed to issue a currency of their own, but the request was refused, and they were further prohibited from exporting the Japanese copper coins to the Loochoo. During the visits of Chinese Envoys Chih were used in defraying their expenses, Kwanyei currency was kept carefully on hand from their sight.

The language of Loochoo is closely allied to that of Japan, its affinity with the Satsuma being very marked. It resembles Japanese in its polysyllabic character of its words, in the use of honorific suffixes with verbs, in the absence of the sound L, in its affirmative interjection "hai" corresponds to the Hē, Hāi, Nē, Nā, &c., and in the fact that, though the terminations are different, the roots of most of the verbs are the same. Add to this that numbers of words are the same in two languages, like Tai, Uma, Ushi, are the same, and it will not be saying too much to say that the language of Loochoo and that of Japan are identically the same in origin.

The chief differences between Loochoo and present Tōkiō dialect in Japanese are as follows: Ki in the Yedo dialect is replaced by Chi, Shi becomes Si, and O, in many words, is replaced by U. Examples of these changes may be found in the following words:—

JAPANESE.	LOOCHOO.
Kikimasenu (present tense negative form of verb "to hear").	Chichabrian.†
Gosho (castle).	Ushui.
Ozato (name of district).	Ufuzato.
Otoko (man).	Uykega.
Shima (island).	Sima.
Heimin (collective name for lower classes).	Feimin.

The sound of F in Loochooan is peculiar, pronounced as if it was written Fw. This is another peculiarity in the language which distinguishes it from any other known tongue. The extraordinary pronunciation given to certain words. The only thing to which it can be compared is the sound of a double consonant in Japanese, as expressed in the words "amafu" and "fufu." The peculiar accent rendered here in the double consonants is given in the case of "amafu" and "fufu." To take one or two instances, in the word "fufu" (merchant), "Fiyēbara" (namet), "Samurēye" (Samurai), this peculiar pronunciation appears. It is a long drawn vowel, the tone of the voice of the person speaking rising higher as the sound is uttered, and the pronunciation cannot be rendered in our system of trans-literation would convey it

\* Bird, horse, and cow.

† The connection between the terminal used here and Japanese terminal Haben is clear.

rd to be understood. There are, of course, words in Loochooan, such as "sidégafu" funaye" (thank you), and "So" (father), gin of which is distinctly foreign.

#### GENERAL REMARKS.

well known that Loochoo has no standing There have been no soldiers since its subby Satsuma in the beginning of the seven-century. The coincidence of this date with suma invasion suggests the probability that the conditions enforced by the conquerors at the population should in future be entirely ad. This condition, if it was enforced, has ly been fulfilled to the letter—not a sword instrument of warfare of any kind is to be the country; and the small guns which eted the armament of the junks which used the voyage to China were borrowed from suma clan.

roads in Loochoo are of a very poor ion. Certainly the streets of the towns of Nafwa, Tonau, and Kumei are fairly well ted, and the paved road leading from to the castle at Shiuri, in spite of the rity with which the stone paving is laid, ompare favourably with some of the better roads in Japan. But, as soon as the leaves the neighbourhood of the towns, hes the open country, the roads become acks, quite impassable for any wheeled nce, and the absence of bridges is marked. e of the roads is sufficient to account for that such a thing as a cart is unknown in try. The transport of produce is con-ither by pack-horses, or by coolies of both he women carrying the load on their heads, e men carry it slung on a pole as in China an.

are very few shops in Nafwa and the owns, and none in the villages. Those xist are of the poorest kind. The buying ing of wares is carried on in the open air, efly by women, each town having several places, in which numbers of primitive e to be seen. A Loochooan stall is a very onstruction. A large umbrella is fixed in the ground, and serves as a protection sun and rain. Underneath this sits the woman with her stock-in-trade arranged ber in small trays or baskets. In some d especially in wet weather, an additional le is made by propping up pieces of oil- o as to form a screen all round the stall-

The articles thus exhibited for sale are h as afford any strong temptation to a er, and consist chiefly of eatables of various uit, meat, &c., and also toys and ornaments hair. The produce from the surrounding is brought in every morning by women to ns and sold in the markets. Lacquer ware use kind and earthenware are made chiefly r, and very little is to be seen exposed for the shops of the manufacturers. There is e village in Loochoo where potteries exist, s is in the immediate neighbourhood of

posited in the family vault, where it is left for three years, until it has become thoroughly decomposed. The jar is then taken out, and the bones being removed and washed, are put into another jar, and replaced in the tomb. As in China, it is customary to hire professional mourners, whose business it is to cry at funerals; but the burial service is conducted according to Buddhist rites.

The division of the people into the two classes of "Shizoku" and "Heimin" has been attended with the worst consequences; it has had the effect of enervating the one class and degrading the other. The Samurai of Japan formed a vast standing army; they were the product of a military system, which had for one of its objects the independence of the country; and though the privileges of their class were only maintained at the expense of the rest of the nation, there is no doubt that the military spirit thus fostered elevated the national character, and gave it a tone of independence which it otherwise would have lacked, and which can be traced in the Japanese farmer of the present day. In Loochoo the same class distinction exists, with all its faults and none of its advantages. The Shizoku of Loochoo has no spirit, no pride of country, and his pride even of self does not rise beyond the empty pharisaical boast that he is not a Heimin. The Heimin is an ignorant serf, who knowing that he is working for others and not for himself, has no heart in his labour, and lives from hand to mouth; and whose highest sentiment is a feeling of stupid respect for the privileged classes. The Loochooan Samurai is thus infinitely below his counterpart in Japan, while the peasant of Loochoo is even more immeasurably inferior to the Japanese farmer. Both classes live and think in the same grooves as centuries ago.

The hair-pin is the chief distinction between the two classes, that of the Shizoku being of silver, while that worn by the Heimin is made of brass. But there are other distinctions. Thus the Heimin is not allowed to wear clogs, he must not carry an umbrella as a protection from the sun, though he may use it in wet weather, and in the making of his clothes he is debarred from using cloth of certain patterns. Marriages between the two classes are very rare. There is one point, however, in which the Heimin of Loochoo had the advantage over the Japanese farmer under the feudal system. He is allowed to ride; and it is acknowledged that that the farmers are better riders than the Shizoku. At the races, which are held at stated times during the year, no prizes are given, but the losers dismount, and forming into line, salute the winner as he rides past.

I cannot leave this subject without pointing out what appears to me to be a curious fact in connection with the social division existing in Loochoo. This is, that while the men belonging to the Heimin classes are almost dwarfish in their stature, physical development, and the shape of their limbs, the Shizoku are, as a rule, fine big men, and are undeniably well made. Moreover, while the former in physiognomy resemble the Chinese, the latter have all the features of the higher classes in Japan. It may be that the degraded condition of the Heimin during many hundreds of years is sufficient to account for this distinction of feature and physical development,

oochooan graves are similar to those in China, mode of interment differs. After death y is placed in a large earthen jar, and de-

but the existence of this clearly-marked difference leads one to suppose that a fusion of races has taken place at some remote period. I have been informed by a friend that he had occasion to observe the same thing amongst the Koreans.

That the hair-pin is one of the distinctions between the Shizoku and Heimin has been already stated. It serves to mark other differences of value. Thus, a Loochooan of the rank of Oyakata wears a hair-pin the head of which is gold but the rest silver. Again, that worn by the Sandzukwan and highest nobility is made entirely of gold.

The following explanation of the origin of the Loochooan hairdress is taken from a Japanese work on Loochoo:—

"In Japan, as it was in the reign of Saikō Kunō (A.D. 593—629), and before that date, it was customary for Japanese to wear hair-pins, which were worn in the queue, in a fashion similar to that now obtaining in Loochoo. The intercourse existing in that reign between Japan and Loochoo led to ranks and incomes being given by the Government of Japan to Loochooan nobles, and, as it was then customary in Japan to distinguish rank by the hair-pin, which was of gold or of silver, according to the status of the wearer, the practice was by degrees translated to Loochoo, and has continued up to the present time."

*Relations between the Sexes.*—The seclusion in which Loochooan women of the upper classes are kept is evidently a custom borrowed from China. It is considered a disgrace for a woman to be seen in public, and those who can afford the luxury never allow their wives to stir out of the house except in a covered palanquin. So strict are the rules affecting the intercourse between the two sexes that a Loochooan woman of the Shizoku class who meets an acquaintance of the other sex in the streets is not allowed to speak to him; both pass each other as if they were strangers. Nor is it considered proper for a man's wife to be seen by any visitor, except it be an intimate friend. To such a pitch is this feeling carried that persons have been known to live for years in the residence of a Loochooan without once meeting the mistress of the house.

In the construction of their towns the Loochooans resemble the Chinese and Koreans. It is true that the internal arrangement of a Loochooan house, in everything except the absence of cleanliness, is very similar to that of a Japanese dwelling. But here the similarity ends. In the roughly formed red and black or red and white tiles, of which the roofs are made, in the high walls, raised so that only the gables of the buildings are visible from the streets, in the arrangement of the courtyard, which suggests the idea of a fortification, and in the loftiness of the rooms, we see another influence at work. To any one coming from Japan, the first sight of a Loochooan town is rather pleasing, probably because it is so very different to anything in Japan; but, after a time, the long lines of walls on each side become excessively wearisome to the eye, and one misses the tasteful arrangement of garden and fence, which are such a pleasing feature in Japanese towns. The Loochooans, however, cling to their walls as to all their other peculiarities. They serve, so they say, "As a protection against fire, wind, and thieves, as boundaries between streets and compounds, and are useful in

the interests of privacy." The last advantage, probably, that which carries most weight

#### SHIURI.

Those who in Shiuri expect to see remarkable, either in architecture or other respect, such as is generally to be in the capital of a country, will be disappointed only two and a-half miles from Nafwa, its white towers are clearly visible from the anchorage. The town is grouped pictorially on the slopes of a hill, on the west stands the palace, or castle, commanding a view of the sea to the south and the grounds of the palace are enclosed with a wall, and there are two gates by which one may be had to the interior. The principal entrance is through a gate, which opens on to the town from Nafwa. After passing through this gate, always ascending, the visitor finds his way to a large courtyard, some 60 yards by 30, paved with red tiles, placed closely together, and not to cover the whole space enclosed, but to form a series of walks. Facing the entrance is an audience hall, or Shō-in. This building is in shape the large gateways built at the entrances of Japanese temples; the front walls are of red and blue, and the roof is tiled in the same manner. Anything more ugly can be conceived. To the left are the offices of the Council of State, the principal hall of which is as a guest-chamber. The ceiling and the walls of this room are ornamented with rough representations of tigers, cranes, and deer. To the right of the entrance is a low building, a suite of rooms occupied by members of the household, and through these a passage leads to the king's apartments, which are at the rear of the audience-hall. The grounds of the castle are picturesque, and show evidences of former care in construction, but little attention now to be bestowed in this direction. The castle has much to recommend it. From the top of the castle we looked out on a succession of green hills, sloping down to the sea, rich with barley and sugar-cane, and with rice; and when we turned from the prospect and observed the marks of decay everywhere—the untrimmed walks and shrubs, tropical luxuriance choked with weeds, and the great precaution is needed so as to prevent falling. The Loochooans claim a great antiquity for the castle at Shiuri, and state that the buildings stand now are, except for the fact that they have been repaired whenever necessary, identical with those originally erected. It is probable that the castle stands much as it was 600 years ago. The population of Shiuri is 40,000, of whom three-fourths are Shizoku. These figures on the authority of my informants, but they appear rather low. 30,000 would probably be nearer the mark. Paper on which anything has been

at respect, and small stone erections in if boxes are to be seen by the road side. provided with cavities in which any old paper, on which characters have been placed and burnt. It is considered proper to throw such pieces of paper spite of this custom, which would seem a great respect for literature on the part of the Loochoos, it is a singular fact that there is no shop anywhere in Loochoo. The only thing is the calendar which it is customary for the Loochoo Government to issue provisionally until the Chinese calendar is obtained.

8. shipbuilding the Loochoos have the Chinese model, and it is the exception the vessel rigged in Japanese fashion. The junks which used to cross over to and the sugar junks which, until the last 30 years when they have been superseded by the carriers of the sugar to the markets in and Osaka, are large vessels some 80 ft. length, with a beam measurement of 12 ft. and a similar depth of hold. In every way they are like Chinese junks even to the rigging in a conspicuous place.

#### DISCUSSION.

Mr. Cook said there was so much matter in the paper that it was very difficult to discuss it thoroughly; but it was very valuable, when printed, for future reference.

Mr. Cook said it was the opinion of the Loochoo, that if he went down to the Universities of Cambridge, and asked any of the students if they knew of a hundred words which would be able to describe the Loochoo; but he remembered reading of it as being in Hall's voyage, and had lately looked and made a few notes, which might be of use. The Captain had fixed the latitude and longitude, and said the religion was similar to that of the Chinese, and that there was an observatory there, as only permitted to the king, and the Loochoo hardly used. Capt. Maxwell, of the *Albatross*, was, which was dressed by the native people made of eggs and flour, and it was found in a hen's skin. Captain Maxwell made a thermometer, and Captain Hall of a clock, which were carefully preserved. He said there were no deformed or diseased people, except a few who were marked with scars. He referred especially to the honesty of the Loochoo, when a watch, which had excited great interest, and it was feared it was lost, it was found next morning, and the bringer refused reward. Captain Hall left them a sextant, and showed them how to use it.

Mr. Cook remarked that there were few more interesting than Captain Hall's travels. In connection with Loochoo, he remembered his narrating of his voyage he touched at St. Helena, and was then residing, and found that the Loochoo was much interested in hearing of them when he was told that in Loochoo there were soldiers and arms, it was quite beyond his power to say more.

Mr. Cook said they were much indebted to the author for the paper, but there was perhaps one oversight in it, there were no means of judging of the value of the Loochoo in English money. It was very

interesting to hear of a nation where there was no army, for he believed the worst expenditure of any country was that on armaments, though it might be necessary.

Mr. Hyde Clarke said it would no doubt be desirable to reduce the few prices and quantities given in the paper into their English equivalents. The sugar crop was very considerable according to the figures given, but the price was very low. He did not know why everybody should be supposed to know the exact locality of every place on the globe; but the book to which Mr. Cook had referred was at one time very familiar, and no doubt thousands of copies were in existence. Since it was published, however, many other places had grown up into more importance, and the instance given of Chicago was very much to the point. It had rapidly sprung up into an immense city, whilst Loochoo had remained practically stationary. The relations of the Loochoo language were, of course, the same as those of the Japanese, as they are allied languages or dialects. Mr. Aston, a distinguished scholar of the Japanese Consular Service, had given in the last volume of the "Transactions" of the Royal Asiatic Society, a most valuable paper on the relations of the Japanese to the Korean. The Korean, and others in Western Asia, and also in America, were allied; but for reasons into which he need not go, it was requisite to go further afield, in what are called Turanian languages, to ascertain the real position of the Japanese, and, consequently, of the Loochoo. With this he had dealt at some length, as quoted by Sir E. J. Reed, M.P., in his paper, and particularly in his appendix to the second volume. The result at which he had arrived, was that the Japanese belonged to that earliest epoch of cultivation, in which were placed the Akkad-Babylonian, the Khita (with some Hittite), the Egyptian, Etruscan, Chinese, &c. All such as these have words which are identical, but these resemblances are distributed in various proportions. The cause was that the words were not derived from one primeval language of identical roots, as generally conceived, but from a variety of words for the same idea. The identity was not to be traced so clearly by similarity of sound, as by identity of psychological relations. Thus if we examined the Japanese or Loochoo numerals, 3 will correspond with Ear, 4 with Good, 5 with Arrow, 10 with Far. These were widely distributed laws of prehistoric language, dependent on various circumstances. In a system of numerations in which the eye figured as 2, the ear was 3. The Japanese have not preserved the relations of 2, but they have of 3. The arrow in the ancient Fetus mythology had a numeral relative, as all weapons and other objects have. Although we cannot, at present, trace Japanese and Loochoo migrations in detail, we know this, with certainty, that the origin of the language and mythology was most ancient, and constituted in forms corresponding with those of the founders of civilisation in the old world. At the present moment the difficulties of tracing each movement or phenomenon were very great, because many ancient forms are unknown; but with the advance of knowledge, we should, no doubt, obtain fuller results. At all events, it might be determined that we were not to regard Japanese as derived from Korean or from Chinese.

Mr. Sayamatsu said there was a great resemblance between the language of Japan and Loochoo; and he had been told by a gentleman from the southern part of Japan that he had been in Loochoo, and that there were very many words which were identical. The most remarkable coincidences were the numerals. He did not say that the Loochoo came from Japan, because the Japanese must have come from Loochoo. The date of the conquest of Loochoo by the Japanese was the 11th century, and even before that there were

records relating to the island. The fact that the king of Loochoo paid homage to China as well as to Japan could not be taken to be of much value, because in China all diplomatic messengers were said to be bringers of tribute; and probably on the same ground even England might be claimed as a tributary of the celestial empire. Japan actually conquered the island a little over 300 years ago; before that the King of Loochoo used to send tribute to Japan, but at that time, owing to internal disturbances, he neglected to do so. When tranquility was restored in Japan, and war was made on the Korea and China, the King of Loochoo was ordered to pay a share of the expenses, and as he did not do this, the Japanese Government sent and conquered the island. Since that time no doubt a certain tribute had been sent to China, but it was never recognised by Japan. Considering the position of Loochoo, it was very important to Japan that it should not be under foreign influence, and therefore when it was apparent that the king was still keeping up relations with China, the Japanese Government could not pass it by, and that was the origin of the so-called annexation.

Mr. Pfoundes said these islands were, in the first instance, made known to Europeans by the early voyages of Albuquerque. The Portuguese entered the Chinese sea about 1511, and, about 1516, they got as far as Canton. Albuquerque, the first Governor-General of the Philippine Islands, sent out an expedition in 1517, which, in the Formosa Channel, fell in with the Loochoo junks, which, it was supposed, were making their annual voyage to Loochoo. It was then a question with the Portuguese whether they might not push forward as far as Japan, which had been so much spoken of by Marco Polo, but their outrages on the coast where they landed, caused the repeated destruction of their settlements in the first year of the 16th century, and they were finally driven down towards Macao; their ill-repute gradually spread through the islands up to Japan, and intercourse with them was more or less cut off. The information with regard to Loochoo had been very admirably condensed in the paper, and there were very many points he should have liked to touch upon had time permitted. Every one would agree that it was a specimen of the first-class work done by the gentlemen of the Consular service, and he must, himself, tender his thanks to the Chairman for allowing him to make researches which were of the greatest interest. These islands, though they appeared very small on a Mercator chart, were in reality of considerable importance, and would prove still more so in future. Dr. Beltelhemier, when he landed, found some nuisances there, but though no doubt his conduct was very heroic in remaining for a long time in the face of annoyances purposely inflicted in order to make him leave the island, he feared he had not that tact which was requisite for making successful efforts in the country. This was one reason why so little had been done by medical or purely religious missionaries. The eminent Chinese scholar, Mr. Alexander Wylie, told him that he knew of the existence of a Hebrew manuscript, written by Dr. Beltelhemier, addressed to the Hebrews in China, but as the fact was there were no Jews in China, he believed it still remained undelivered in the hands of some of the missionary authorities.

The Chairman said the paper was a very suggestive one, but no doubt it would be improved by the addition of the English equations for the measures and prices. He had tried to roughly do this, and he found that the area of Loochoo was rather less than 1,000 square miles, and the population 166,000, which was very large for so small an area, considering that a great part was barren rock. The annual production might be estimated roughly at £100,000, which was probably a low estimate; it struck him as being exceedingly low—scarcely more than 12s. per head. He had no doubt, however, that the production was very low, as the condition

of the people was really one of considerable poverty. Their import and export trade amounted, in numbers, to something like £77,000, which was small for such a population. The value of the produce was not such as would have any appreciable effect on our consumption, being about £20,000. He thought the quantity was probably rather less than 1,000 tons. It was a dark, black kind of sugar, only used by the Japanese, and they used much more Chinese sugar, which was of a better quality. There could be two more opposite instances than China and Loochoo—of progress on the one hand, and stagnation and political inanition on the other. No doubt Loochoo had a very ancient history, for the date about it between the Japanese and Chinese was as far as the 6th century. Japan collected in A.D. 616, and China attacked and conquered Japan in A.D. 620. Although so small a territory, it was divided into three rival States, and he had seen the old castles which formed the stronghold of those three States, and was much struck by their enormous strength. It was built of immense stones put together without mortar. The state of things showed the result of non-communication with the world. There were very few nations now existing which excluded themselves from the rest of the world; they were always found to have become stagnant, gone down hill—become fossils as it were. Loochoo was in that condition, but he hoped that a new era would now begin, and that fresh vigour would be shown. Living alone, having nothing to do but make laws for themselves, they went into minute details, and made the most elaborate form of government, embracing so many departments that he had judiciously omitted reading many of them. There was a Herald's office, Woods and Forests, a Library, and every description of office, and, indeed, seemed the only way they had of employing their time. It was a curious fact that this small population was divided into two classes, nearly in the proportion of half and half, so that nearly one half, viz., the lower class, were entirely unproductive. This much showed how it was the population could be kept in check without any particular military display. The Loochoo arms, though at first sight it might seem to be a happy state of things, had not been able to resist Loochoo from annexation, and he feared that when millennium arrived, armies would be necessary which desired to retain their independence. The relations between Loochoo and China and Japan were interesting, and with regard to the language, there was room for much further study, because there was of an earlier language and an earlier character. He had found stones there bearing inscriptions which were neither Japanese nor Chinese, and which the Chairman said was the ancient Loochoo language. The gentlemen in the Consular service would continue efforts to investigate these matters, and succeed in tracing, not only the present dialect but pre-existing ones. In this case they had a text extant, coeval with pre-historic times, and it was very interesting to trace the origin of the language to see whether it came from the north or the south. It was certain that at one time a tide of population ran from the south to the north, for a strong Loochoo element ran through all the islands, right up to the north. He concluded by moving a vote of thanks to Mr. Gubbins for his paper, which was carried unanimously.

Dr. Mann said that he had reason to hope that the service rendered to the Society by the Chairman that evening, would be supplemented by a further contribution regarding the commerce of Japan at the next future session.

The Chairman said it would give him great pleasure to communicate any information he could gather for the practical use of the Society.

## MISCELLANEOUS.

## PRODUCTION AND PREPARATION OF SALT IN ITALY.

Industry of the preparation of sea salt in Italy according to a report recently issued by the United Consul at Milan, in a most flourishing condition, addition to supplying the wants of the Italian themselves, there is annually exported about 80 tons, exclusive of the productions of Sardinia and these islands about 100,000 tons are annually sold. The cost of production of common salt is fifteen lire the ton, and it is estimated that Government realises a profit from this article of 4,000 lire annually. The places of production in are eleven, and almost all are Government property; a part are let to private industry, while five are managed directly by the State. The former are diari, Convecchio, Volterra, Salsomaggiore, Salsomaggiore, and Trapani; the latter at Margherita, Corneto, Cervia, Lungro, and Portoferraro. To hasten the evaporation and produce a good of natural salt, which is the main object of artificial production, a large expanse of level ground, the sea, and as near as possible to the sea level, is enclosed by high dykes to prevent flooding from seas or storms, the surface is subdivided into levels, separated by little banks, as is practised in cultivation of rice. The entire extent of the salt in communication with the sea by means of a which serves for the ingress of the sea water and of the rain-water, and sometimes hydraulic is used to empty or fill the basin. Numerous canals and ditches run in several directions through the extent of the evaporating ground, is by these that the water is guided to the different levels. In April the rays of the sun begin to gain force, and the equinoctial having passed, the damages of the past are repaired, and the rain water that may have been pumped out, generally by hydraulic elevators, is by centrifugal force. The rain water having reached, the canal to the sea lets in the salt water, should cover the ground to the depth of about two feet. The various levels of the salt farm should differ by about three inches, one above the other, so that the water may circulate slowly and freely over the whole expanse. The water, exposed to the sun, and under the influence of the wind, dries, and as it diminishes in volume it increases in density, and it is to facilitate this process that the water is constructed and the water passed from one level to another, until it has acquired the desired density, when it is reunited in deep reservoirs. This process, which is repeated, lasts all through the month of June, it is in the month of June that the real work of evaporating the water for the production of salt begins.

The water collected in the reservoir, and of 15° to 20° Baumé of density, is pumped out into large flat reservoirs until, by evaporation, it reaches 25° of density; it is then spread over the drying portion of the farm in extensive beds, of from 5,000 to 10,000 square yards, to a depth of two inches. The evaporation by the dry wind concentrates the water, and causes it to be deposited; small points are seen forming on the water, which enlarge into crystals and at the bottom, where they increase by the addition of other crystals; this process is slow and does not interfere with by extraneous matter.

The salt reservoirs keep this large flat

expanse continually filled with water to the depth of about two inches; the earth at the bottom begins to whiten, and a crust of deposits is found at the bottom of the water, which augments day by day, until by the month of August it becomes from two to three inches thick. The crop is then gathered, as a rain storm would destroy a portion of it; the superficial water is drawn off, leaving a deposit of salt, which is of a pure white, and shines like crystallised snow. The workmen then enter the salt farms, and with hoes, picks, and shovels separate the crust of salt from the earth, and carry it to the magazines in sacks, barrels, and carts. This work lasts more than a month, sometimes continuing until September, and it is necessary to employ a very large number of men, as a change of weather would have injurious results in the harvest of salt. During the whole of September and a great part of October, the soil of the reservoirs is washed out, and the water deposited in deep reservoirs, where it remains until the next year; the crystals that have been formed are, however, filled with impurities, and have to be subjected to the action of rain water during the winter, before they become saleable. As regards artificial evaporation, the principle that regulates the production of salt by artificial means is practically the same, but the manner of producing it is different, as the expensive process of reduction by fire is adopted. In various parts of Italy, at different depths, are found layers of salt, evidently deposited at remote periods, in strata, or mixed with heterogeneous materials. In all the wells in these localities the water is strongly impregnated with salt. The only two places in Italy where salt is worked by artificial means are Volterra and Salsomaggiore, the former having wells 40 yards deep, often connected by underground galleries, and the latter an artesian well, of the depth of 300 yards. The water, on being pumped out, is deposited in large reservoirs, and afterwards in very large open boilers, under which fires are continually kept burning. The advantage of this system is its practicability at all seasons, and its independence of the weather, but the production of salt is much more expensive. The salt deposited and scraped up from the bottom of the boilers is of the whitest quality, but less granulated than the sea-salt, and is sold throughout Tuscany and in other places at the price of that passed through the mill. The salt wells of Volterra produce annually more than 10,000 tons, and those of Salsomaggiore about 1,000 tons only. The salt of Volterra, on account of its purity, is mostly used for table purposes.

At Lungro, in Calabria, there is a salt mine which employs 400 hands; here the deposits are found in strata slightly mixed with extraneous matter of various formations, horizontal, perpendicular, and often in caves or pockets. This mine dates from ancient times, and has been often abandoned, but is at the present time in a flourishing condition. It is situated at the bottom of a valley, about 300 yards above the level of the sea, and is entered by a small aperture of about three square yards in the side of the Apennines. This tunnel, after a short distance, communicates with a subterranean gallery, descending by easy gradations and steps to the depth of 200 yards; connecting galleries and drifts lead in every direction, and the salt is extracted by blasting, and then broken up into fragments of convenient size for portage. This mine produces about 7,000 tons annually, which is principally consumed in Calabria and the Basilicata; it is compact, pure, and white, like chalk, and translucent. The largest salt works in Italy are those of Cagliari, producing annually more than 130,000 tons of salt. On the coast between Marsala and Trapani, in Sicily, there are many private salt farms, and as no Government monopoly exists, any one is at liberty to cultivate this industry on his own lands. The salt farms of Trapani supply Rome, Naples, and Venice, besides exporting

## KAURI GUM OF NEW ZEALAND.

Consul Griffin, of Auckland, has written a full report on the production of kauri gum, which is largely used for the manufacture of varnish, of which the following is an abstract :—

It consists of the dried and solidified sap of the kauri tree, a species of pine known to botanists as the *Dammara australis*. It is found only in the province of Auckland, in that part of the colony lying to the northward of the thirty-ninth degree of south latitude, and does not exist in any other part of the world. The largest quantity of marketable kauri gum is dug out of the ground. It is found at various depths, from just above the surface of the soil to many feet below the surface. It is found on bare hillsides, on flat clay lands, in swamps, and even in some places that are covered with a more or less thick coating of volcanic *débris*. Sometimes the gum is found in small detached lumps, and at other times large deposits will be found in one hole. On cultivated land it is not unfrequently turned up by the plough, and in many places the cutting of large drains in swamps has revealed large deposits of this vegetable product. In the forks of the large branches deposits varying from a few pounds to nearly a hundredweight are sometimes met with. When a kauri tree is cut in the bark, even one of the largest and oldest, varying in diameter from six to ten or twelve feet, it will bleed like a young sapling. In a few weeks, if the weather be dry, a large mass of half-dried gum will have oozed from the wound, not unfrequently appearing in the form of a great thick band, reaching from the wound to the surface of the soil around the tree. When a tree is felled, the stump bleeds in a like manner until large masses of gum can be broken off from the stump. This "young" gum is white in colour, and has not the rich amber colour which age imparts to it when stored beneath the surface of the soil away from the action of sun and weather.

The gum is not soluble in water. It ignites freely, and burns with a lively sooty flame. It froths and bubbles, and produces a pleasant aromatic odour. The perfume it exhales when burning in the open air is not unlike that of frankincense and myrrh.

any special fondness for the work. They when they become pressed for food and account of the failure of their crops, or of Many Europeans have resorted to this kind but they belong generally to a class who and impatient of the restraints which a civil poses upon them, and who prefer to camp fashion of gipsies, and live in tents and ramp than in houses fitted for civilised beings. I supposed that a European who resorts to is unfitted for any other occupation. He less, dare-devil sort of life, away from kindred, and from the restraints of civiliza

When the gum is taken out of the ground with earth, and its surface is found to be state of decay. When the digger is tired of his gum into a bag and carries it to his tent in the evening or upon rainy days he, wance of his wife and children, scrapes off surface until the clear solid gum beneath. When a sufficient quantity of it has been put into a box or bag and taken to the public house, where it is sold for what. Sometimes the purchaser will assort it, generally sorted till it reaches the city, employs a large number of skilled hands pose. The gum, after it is scraped and packed carefully in boxes, so as to prevent from breaking. It is then ready for export and scrapings are also exported.

Some of the gum is used in New Zealand manufacture of varnish, but in no great quantity. The export of kauri gum for the year 1880 is that of any other year. The total export 3,410 tons, and 3,247 tons was the total export. The invoices thus far received indicate shipment for the year 1880 will be 5,5 price of gum ranges, according to the price from 144 dols. to 720 dols. per ton. The of it, however, is bought at the former average price may be safely set down at 1 ton. At this rate the total value of the export for the year 1880, viz., 5,500 tons, 1,188,000 dols. More than two-thirds of to the United States. It is either shipped and Boston in sailing vessels, or to London shipment to the American cities.

## THE ENGLISH MILE.

we lately read a paper on the "English mile" in the *Academy of Sciences of Paris*, and the conclusion is taken from *Nature* :—

"that the mile of 1,609 metres long passed by geographers and navigators as being of the terrestrial arc of 1': in other words, the degree equal to 60 of those which it contains 60.5; there is thus an error of one-sixth. This error, if it existed long ago, would have been a serious one, but it has been corrected by the discovery of the law of universal attraction. The first person who presented himself to his mind as having failed him, because he made use of the English mile to calculate the radius of the earth, was the great idea presented itself to him of calculating up again when he learned the French measurement of a degree in France. On this defective estimate? Certainly it need not from any defective measurement, for Greek measurements, among those which really made, and not fictitious measurements of Posidonius, are far from presenting a magnitude. English geographers, then, committed some mistake in taking their mile documents.

navigation was limited to the waters of the sea, and to coasting along the western coast, it was scarcely necessary to trouble one of this element, but from the time that the Spaniards and Portuguese opened the Atlantic, sailors were compelled to make use of the matter. I suppose that the geographers applied to their geographers, and did nothing better to consult than Ptolemy, the only authority in these matters. But when he refers to Eratosthenes, he says that the measurements of the latter and found that, viz., 500 stadia for the terrestrial arc thus been led to examine the measurements of Eratosthenes. According to the documents we have preserved, Eratosthenes measured of meridian which separates the parallel of Alexandria, and finally found 700 stadia. This is how he worked:—He measured the distance of the sea at midday at the equinox, and thus found 7° 12', at Syene the bottom of the wells was vertical, the sun on that day, so that Eratosthenes found zero for the zenith distance of that day rather than the Greek astronomer observation to be made at Syene with a instrument then very common in Egypt, distances resulted from an effective observation in the case of Alexandria. We shall conjecture is perfectly justified. We observed observations made on the dark shadow of a constant error equal to the zenith distance of the upper edge of that instrument do not seem to have remarked it, as they deduced from their observations the obliquity of the ecliptic or the epoch of did not concern them, for, by combining as of the summer with that of the winter error in question disappeared from the difference it is exactly the same here, since we have absolute latitude, but with the difference we place at which the centre of the sun is at midday on the same side of the vertical. It is 7° 12' concluded by Eratosthenes as moreover the advantage of not using it by refraction.

Here is a first verification. On opening the *Comptes rendus des Travaux* we find—

For the latitude of Alexandria .....	31° 12'
" " Syene .....	24° 5'
Difference .....	7° 7'

instead of 7° 12'. The difference, whatever may be the cause, is very small.

Here is a second and more delicate verification. The latitude of the point in Alexandria, where Eratosthenes observed, could not differ much from that which we have given. By adopting that and 7° 12' for the zenith distance of the upper edge of the sun at the winter solstice we find  $31^{\circ} 12' - (7^{\circ} 12' + 16') = 23^{\circ} 44'$  for the obliquity of the ecliptic. Syene gives  $24^{\circ} 5' - 16' = 23^{\circ} 49'$ . It is possible that in the year 260 A.D. the obliquity of the ecliptic was from  $23^{\circ} 44'$  to  $23^{\circ} 49'$ . From 1760 A.D. to 260 A.D. is 2,000 years. At the rate of 48" diminution per century the obliquity would be  $23^{\circ} 25' 13'' + 48'' \times 20 = 23^{\circ} 44'$ . The observation of Eratosthenes at Alexandria is then authentic, and, moreover, very precise. That of Syene presents an error of only 5'.

There remains the geodesic operation. Egypt was the only country of antiquity which rejoiced in a survey. The valley of the Nile was very populous at that epoch, as far as Syene, and no doubt the survey extended thus far. Eratosthenes must have had every facility for procuring the necessary documents. He must have taken into account the difference of longitude of 2° 59' which exists between the two cities, without having had to determine it directly. I regard, then, the distance of 5,000 stadia, in round numbers, as being quite as accurate as the other part of his operation, and as applying to the arc of meridian comprised between the parallels of the two cities.

We finally conclude from this 694.4 stadia for the degree. The Greek astronomer gave, in round numbers, 700 stadia. What was this stadium? To reply to this question I calculate the arc of meridian from Alexandria to the parallel of Syene, with the actual element of the terrestrial ellipsoid. It is 797,760 metres. At the rate of 5,000 stadia we find 159,55 metres for the stadium. At the rate of 600 feet for the stadium, the foot adopted by Eratosthenes would be 0.266 metres. This was then the ancient Egyptian foot, which we now reckon at 0.27 metre; and, in fact, it was with this foot that the survey of Egypt must have been made. By this reckoning the 5,000 stadia give  $5,000 \times 600 \times 0.27 = 810,000$  metres, showing a difference of 12,240 metres, partly owing to that of the points of departure, partly to the error which we perhaps make in the length of the Egyptian foot is carrying it to 0.27 metre. Thus the measurement made in Egypt, more than 2,100 years ago, by an able Greek astronomer, is as good as authentic. All the existing causes of uncertainty do not alter it more than one-sixth. It is certainly not from this quarter that the error can come for which we seek.

Nor is it in the measurement of Ptolemy, for he tells us he went through the same operations and found the same results, only he gives 500 stadia to the degree instead of 700. This difference is evidently due to the fact that Ptolemy, who lived 400 years after Eratosthenes, under another domination, did not make use of the same foot. In fact he employed the stadium of 600 Philistrian feet, and as this foot is about 0.36 metre, while the ancient Egyptian foot was only 0.27 metre, he had to reduce 700 stadia of his predecessor to  $700 \times \frac{27}{36} = 525$ , or 500 in round numbers.

These estimates are confirmed, finally, by the Arabian astronomer, who measured, in 827 A.D., an arc of 1° in the plains of Mesopotamia. They found fifty-six miles, and concluded that they had thus verified the number of Ptolemy. The Arab mile being 2,100 metres, the arc

measured is found to be 117,600 metres, which corresponds to a stadium of 235 metres. This is very nearly the Philæterian stadium of 216 metres, except the error of the measurements seven times more sensible on so small an axis, and the uncertainty of our existing estimate of the Arabian mile in the time of the Kalif Almamoun.

To resume: the estimate of Ptolemy is only a sort of conversion of the excellent measurement of Eratosthenes in units of another epoch and of different length. It would thus lose a little of its first precision; but, such as we find it in Ptolemy, the English geographers were fully justified in taking it for the basis of a valuation of the arc of 1' and of offering it to the navigators of their country. Only, and it is here the mistake lies, they believed that the great Greek astronomer of Alexandria must have made use of the Greek foot. This is one and a half hundredths larger than the English foot. If the English geographers of the sixteenth century had strained this valuation ever so little, and had carried it to  $\frac{1}{100}$ ths, they would have found 630 English feet for the stadium, which they believed to be 600 Greek feet, and these 630 feet or 210 yards, multiplied by 500, would give them 105,000 yards for the degree and exactly 1,760 yards for the mile. The English mile, then, has evidently been deduced from the measure of Ptolemy; its error of one-sixth is solely due to the fact that the Greek foot has been confounded with the Philæterian foot.

#### QUININE MANUFACTURE IN ITALY AND GERMANY.

The following account of the manufacture of sulphate of quinine in Italy, with suggestions as to the cultivation of the cinchona tree in the United States by Consul Crain, of Milan, is taken from the *Journal of Applied Science*. The manufacture of salts of quinine is an important Italian industry. It has been carried on at Milan and Genoa since 1870. Twenty-two thousand five hundred pounds are consumed yearly in Italy, of which one half is made at Milan, 6,750 lbs. at Genoa, and the balance imported from Germany. Forty-five thousand pounds of quinine and salts of quinine are produced in Italy. The production of the world is estimated at from 230,000 lbs. to 260,000 lbs. per year, as follows:—Germany, 56,250 lbs.; Italy, 45,000 lbs.; France, 40,000 lbs.; England, 27,000 lbs.; America, 63,000 lbs.; India, 12,250 lbs. The two Italian factories produce 45,000 lbs. of the sulphate of quinine, viz., 40,500 lbs. at Milan, and 4,500 lbs. at Genoa. The first of these employs 45 hands, the second 15. The Milan factory ships largely to all parts, furnishing large supplies to Russia, France, and Austria. England receives two-thirds of her supply, and Holland one-half of hers from the same source. Efforts will be made to acclimatise the cinchona in Italy, to increase the supply and lessen the cost of the product. Its successful culture in India and Ceylon encourages the belief that it will grow wherever the soil is dry, the rainfall large, and climate temperate. Many parts of the United States fulfil these conditions, and notably where its product is needed. The culture of the cinchona in America would cheapen an indispensable medicine, and open a new industry to capital and labour. In this connection some facts reported by Mr. E. Van Estvelde, the Consul-General of Belgium in India, are instructive. He reports that the best varieties of cinchona have been successfully acclimatised in British India. The Government there cultivate chiefly the *Cinchona succirubra*, which contains a large quantity of febrifuge alkaloids, and the *Cinchona calisaya*, which is better suited to the manufacture of quinine. The culture of the first has been successful. Uncertainty still exists as to the *Cinchona calisaya*, and the Bengal Government are examining the plantations of Java,

where it has been cultivated with entire success. cinchona plantations are in two distinct India—in the north of the Neilgherry Hills, Madras Presidency, and on the slopes of the Nilgiris. Those of the Government are as yet unimportant, covering 1,300 acres on the Nilgiris, and nearly 3,000 acres in Sikkim. There are private plantations of later date already considerable. The red bark (*Cinchona*) has many febrifugal alkaloids, but little quinine was important, therefore, to determine the value of the alkaloids and the cheapest method of extraction, in order to furnish a good febrifuge at a moderate price. The Medical Commission recommended the extraction of cinchonine, cinchonidine, and quinine by simple means, and the Government sells a mixture of these three alkaloids under the name of "Cinchona febrifuge." As the price of this mixture exceeds 2s. 7d. per oz., this febrifuge is used only in the hospitals of India, and sold in large quantities to the public. The chief surgeon of the province reports that the doctors are unwilling to declare that the "Cinchona febrifuge" is a medicine of recognised efficiency in the treatment of ordinary intermittent fevers, and that the excellent prophylactic for those who live in marshy countries. Most doctors are of the opinion that it is inferior to quinine as a therapeutic agent, that its effect is slower, and that it is insufficient to cure severe intermittent fever. That it is a medicine of value is shown by its use in the Indian hospitals, which, as the following figures show, is remarkable:—1874-75, 18,750 lbs.; 1875-76, 1,940 lbs.; 1876-77, 3,750 lbs.; 1877-78, 5,162 lbs.; 1878-79, 7,007 lbs. The hospital at Calcutta consumed more than 5,500 lbs. in 1878-79, and, as the use of quinine diminished in the same time about as much, considering the cost of the last-named alkaloid, the Indian Government saved about £25,000. At the same time the Government chemist of India is trying to produce a better febrifuge, by mixing three sulphates, cinchonine, cinchonidine, and quinine, of which the cost would be a little higher. Financially, the Government of Sikkim gave last year a net profit of £4,000, although not fully developed, or  $\frac{1}{3}$  of the sum invested.

From an official report recently published that within the German Empire there are 18 manufacturing establishments, of which Prussia, Wurtemberg, Brunswick, and Hesse have one each. The most important German establishments are those of Frankfort-on-the-Main; of Böhrlingen, in Baden; and of Jobst, in Stuttgart. The Zimmermann establishment was founded by Dr. Conrad Zimmermann, and has since acquired considerable renown. It is a very complete and extensive manufactory; it produces about 50 bales of cinchona bark, and produces 100 kilos. of quinine daily. The principal preparations of the German establishments are the sulphate of quinine, the muriate of quinine, and the hospital quinine, made from various alkaloids. The sulphate of quinine produces very little; while the cinchonidine is manufactured in large quantities, especially for export to the States. The efficacy of this drug is similar to that of quinine, while its price is only one-third or one-fourth that of the sulphate. Amongst the numerous other salts and preparations of quinine made in Germany are chiefly to be mentioned the preparations of the amorphous quinine, the muriate. These preparations, being soluble, are much employed for injections in the treatment of fever resulting from wounds, and are of great importance to army hospitals. The manufacturers get their cinchona bark from London or Paris, which are the principal sources of that commodity. The bark is also brought to Amsterdam from Java by the Dutch Govern-

years occasional lots have been imported at

inner factory at Frankfort, two or three years  
eight large territories in Java, and now employs  
hundred natives in clearing ground and plant-

### THE ASSOCIATION MUSEUM AT YORK.

British Association for the Advancement of  
having decided to hold its annual meeting this  
York, where, fifty years ago, its first meeting  
it has been thought that advantage should be  
this jubilee meeting to show, as far as possible,  
press which has been made during the past half  
in the construction of instruments of scientific  
and, with this view, it has been decided to  
men of science, scientific societies, and manu-  
to exhibit, at the meeting, instruments of the  
externa, and tools used in their construction;  
the science be fifty years old, the instruments  
1831; otherwise specimens of the earliest  
that can be found.

proposed exhibition will also include apparatus  
specimens illustrative of papers to be read at the  
tion meeting, which the authors may be willing  
to be examined at leisure, as well as instruments  
used for the prosecution of special researches  
have not yet become articles of ordinary com-

It is very desirable that such instruments and  
has should be exhibited in action, if arrange-  
can be made for the purpose.

exhibition will be for the week of the meeting  
is, from the 31st August to September 8th. To  
that specimens entrusted for exhibition shall be  
antagonously placed as possible, a special sub-  
committee, called "The Museum Sub-Committee," has  
arised at York, who will afford every possible  
attention.

Notations for space should be sent to the Hon-  
aries, British Association Offices, 17, Blake-street,  
as early as practicable, but in any case not later  
as 15th day of July, 1881.

### ARTIFICIAL SEASONING OF TIMBER.

C. René, pianoforte manufacturer, of Stettin,  
my, as reported in *Engineering*, has devised a plan  
in he utilises the property of oxygen, particu-  
of that ozonised by the electric current, to  
fully season the timber used for the soundings  
of musical instruments. The first impulse to  
ments being carried out in this direction was  
by the well-known fact that wood, which has  
seasoned for years, is much more suitable for the  
lecture of musical instruments than if used soon  
it is thoroughly dried only. Mr. René claims  
instruments made of wood which has been treated  
oxygen process possess a remarkably fine tone,  
not only does not decrease with age, but as far as  
ience teaches, improves with age as does the tone of  
famous old violins by Italian masters. We are  
told that the sounding-boards made of wood pre-  
in this manner have the quality of retaining the  
longer and more powerfully. A number of pianos  
featured at Mr. René's works, and exported to  
ages several years ago, have stood exceedingly  
and seem in no way affected by the climatic  
as they are exposed to. While other methods of  
gassing woods with chemicals generally have a  
counting influence on the wood fibres, timber pre-  
by this method, which is really an artificial  
g, becomes harder and stronger. The process is,  
to be regularly carried on at Mr. René's

works, and the apparatus consists of a hermetically  
closed boiler or tank, in which the wood to be treated  
by the process is placed on iron gratings; in a retort,  
placed by the side of the boiler and connected to it by  
a pipe with stop-valve, oxygen is developed and ad-  
mitted into the boiler through the valve. Provision is  
made in the boiler to ozonise the oxygen by means of  
an electric current, and the boiler is then gently fired  
and kept hot for forty-eight or fifty hours, after which  
time the process of preservation of wood is complete.

### ACTINIC BALANCE.

Professor S. P. Langley, of the Alleghany Observa-  
tory, U.S., has devised a new instrument, which is  
said to be considerably more sensitive and accurate than  
the best thermo-pile, and which he terms an actinic  
balance. The principle of the apparatus is explained  
as follows:—A differential galvanometer, that is, a  
galvanometer with two equal coils of wire wound  
oppositely round the needle, has each coil connected  
in circuit with a strip of thin steel, and the same  
electric current is split up between them. If the  
resistances of the two steel strips are equal, the current  
will be divided into two halves, one half traversing one  
coil and the other half the other coil. These two currents  
will neutralise each other's influence on the needle, which  
will remain undisturbed. If, however, the temperature  
of one strip is raised above that of the other by exposure  
to a source of heat, the hotter strip will increase pro-  
portionately in its electric resistance, and the balance of  
currents on the needle will in turn be proportionally  
disturbed. The deflection of the needle will in fact  
indicate the change of temperature in the exposed strip.  
The strips employed by Professor Langley are thin steel  
bands  $\frac{1}{16}$  millimetre thick,  $\frac{1}{4}$  in. long, and  $\frac{1}{16}$  in. wide,  
and several of them are placed side by side to get a  
broader surface exposed to the heat rays. As at present  
constructed, the instrument is said to be from 5 to 100  
times as sensitive as the most sensitive thermo-pile, and  
its sensibility can be increased by coating the strips with  
lamp-black.

### CORRESPONDENCE.

#### BAMBOO IN CEYLON.

In the discussion that took place after the reading of  
Sir Arthur Phayre's paper on British Burma, on the  
13th May, I see that a quotation I read, bearing on  
the growth of bamboo, from the *Gardener's Chronicle*, of  
the 30th of April, is (inadvertently) omitted, referring  
to the Royal Botanical Gardens at Peradenya, Ceylon.  
H. J. E., a keen observer, writes:—

"Perhaps the most striking objects in these gardens  
are the extraordinary clumps of giant bamboo, which  
exceed anything I have ever seen or heard of. In some  
of them not less, and probably many more, than 200  
culms of over 100 feet high are growing, as tightly  
packed together as possible. Some of the stems must  
be very nearly, if not quite, a foot in diameter, and the  
average, eight or nine inches. This splendid bambo-  
o is, I believe, a native of the Malay Peninsula, and is  
the most remarkable instance of rapid growth I know  
of, each of these immense stems being formed in a few  
months."

To lovers of botany, a fine specimen of this bamboo  
may be seen at the Duke of Northumberland's garden,  
at Sion-house, Chiswick. I have a stem here from that  
clump, nearly 70 feet high, the top of which pushed its  
head through the roof of the conservatory.

THOMAS ROUTLEDGE.

Clapham, Sunderland, 26th May, 1881.

## NOTES ON BOOKS.

**New Commercial Plants and Drugs, No. 4.** By Thomas Christy. London: Christy and Co. 1881.

Among the commercial plants described by Mr. Christy are the Ceara, the Mangabiera, and the Apocynaceous rubbers, Landolphia, from Western Africa, and Chinese and Japanese peppermint plants. Chaulmugra oil, as a substitute for cod liver oil, varieties of bark, caroba leaves, Chian turpentine, and some plants already noticed in this *Journal*, are included under the head of new drugs. The descriptions of eleven new drugs from Japan, used for rheumatism, congestion, and many other diseases, conclude this part. One of them—mahng dah-rah-gay (*Datura atiba*) is used by the natives of India for poisoning, and professional poisoners are often called dhatureas, on account of the use made of this drug.

**Water-works Statistics, 1881.** Edited by Charles W. Hastings. First issue. London. 1881.

An alphabetical list of towns is here given, with particulars in columns of source of supply, price, dividends, and other information. One hundred and thirty-four towns have made a return; 108 give source of supply, 131 state whether the supply is obtained by gravitation or pumping, 69 quantity raised per annum, 127 rental or assessment, 86 meter charge, 90 price per 1,000 gallons, 99 number of meters in use, 130 if constant or intermittent service, and 46 amount of dividend.

**Gas-works Statistics, 1881.** Edited by Charles W. Hastings. Third issue. London. 1881.

Returns from 726 towns in the United Kingdom are here given, which contain information respecting the number of tons of coal carbonised, the make of gas, illuminating power, price per thousand cubic feet, price paid for public lamps, and amount of dividend. About half the returns also give the illuminating power of the gas, and 200 the price realised for coke.

**The Gas and Water Companies' Directory, 1881.** Edited by Charles W. Hastings. Fifth issue. London. 1880.

This volume contains the dates of formation, the capital, the names of the engineers and secretaries of the companies, besides other information, and the population of the places, as well as their distance from London.

## GENERAL NOTES.

**Glass Making.**—The following statistics relative to the manufacture of glass in the United States for the year ending May 31, 1880, compared with the results obtained by the census of 1870, is obtained from a preliminary report of the Census-office:—

	1880.	1870.
Number of establishments	194	154
Employees	23,822	15,867
	Dols.	Dols.
Capital	19,415,599	13,828,742
Wages paid	9,112,801	7,588,110
Materials used	7,891,308	5,904,385
Value of product	21,603,464	16,470,507

The investigation into the growth and exudation included only those works which issued from the crude material, and not those in which fused glass is a raw material, such as was painted or stained glass, mirrors, chemists' ware

**Colour of Seeds.**—Mons. Panchon has series of experiments with beans, on the influence of colour of seeds on germination, with this result, in order to reach the same visible stage of black or violet seed absorbs more oxygen than the yellow one, though a more rapid germination in the latter. On the other hand, the quantity of acid exhaled by white seeds are found to be greater than those from the dark, sometimes. These differences are considered to prove that seeds are better conditioned from a physiological view. In the natural state, i.e., when the seed is in light—the conversion of legumin into aspartic acid on much more easily in the coloured seeds than in the white. "The more frequent and pronounced pigment of northern lands is, therefore," says M. Panchon, "a favourable circumstance for the growth of the seed under the peculiar light-conditions to which it is subjected."

## MEETINGS FOR THE ENSUING WEEK.

**MONDAY, JUNE 5TH.** Royal Institution, Albemarle-street, 8 p.m. General Monthly Meeting.

Geologists' Association, University College, London, 8 p.m. To the Isle of Wight.

**TUESDAY, JUNE 6TH.** Royal Institution, Albemarle-street, 8 p.m. Prof. Merley, "Thomas Carlyle."

Biblical Archaeology, 11, Hart-street, 1. Mr. Theo. G. Pinches, "Remarks on coveries of Mr. Rassam at Abou-habba." "Notes on the Recently-discovered Pyramids of the VI. Dynasty." 3. Prof. E. B. "Description of Mentubotap." 4. Mr. "Was Piankhi a synonym for Sesostris?" Zoological, 11, Hanover-square, W., 8 p.m.

**WEDNESDAY, JUNE 7TH.** Geological, Burlington-house, 8 p.m. Prof. H. G. Seeley, "The Reptile Gower Formation." 2. Prof. T. McK. "Basement-beds of the Cambrian in the Isle of Wight." 3. Mr. J. S. Gardner, "Description and Correlation of the Bournemouth Beds." Part II. "Lower Series." 4. Mr. Robert F. Tomes, "New Species of Coral from the Middle Devonian." Microscopical, King's College, W.C., 8 p.m. Royal Literary Fund, 10, John-street, 3 p.m.

**THURSDAY, JUNE 8TH.** Royal Institution, Albemarle-street, 8 p.m. Prof. C. E. Turner, "Russia (Lecture III.) "Tourgenieff."

Inventors' Institute, 4, St. Martin's-place, 8 p.m. Mathematical, 22, Albemarle-street, W., 8 p.m. Cayley, "The Gaussian Theory of Surfaces." "System of Co-ordinates Discussion of all Non-Metrical Properties of Cubic and Bicircular Quartics with 3. Mr. J. J. Walker, "A Theorem in Operations." 4. Mr. J. W. L. Gladstone, "Symbolic Operators."

**FRIDAY, JUNE 9TH.** Royal United Service Institution, 1, Whitehall, 8 p.m. Captain Walter James, "Lion."

Royal Institution, Albemarle-street, W., 8 p.m. Meeting. 9 p.m. Prof. Downes, "Origin of Spectra."

Astronomical, Burlington-house, W., 8 p.m. Gresham Microscopical Club, University College, 8 p.m.

New Shakespeare, University College, W.C., 8 p.m. "The Alterations in the Acts of Shakespeare's Plays."

**SATURDAY, JUNE 10TH.** Physical Science Schools, 8 p.m. 1. Prof. W. Chandler, "Hardening of Steel." 2. Mr. W. Gass, "Electromagnetic Induction."

Royal Botanic, Inner-circle, Regent's-park, 8 p.m. Royal Institution, Albemarle-street, W., 8 p.m. C. E. Turner, "Russian Literature." "Nekrasoff."

## OF THE SOCIETY OF ARTS.

No. 1,490. Vol. XXIX.

RIDAY, JUNE 10, 1881.

For the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.

## NOTICES.

## MR. BUCKTON'S LECTURE.

ry to the Domestic Economy Congress,  
n, author of "Health in the House,"  
at the Royal Albert Hall, a lecture  
her method of teaching Domestic  
Leeds, with copious diagrams and  
on Thursday, June 16th, at 11.30 a.m.  
ay be obtained on application to the  
the Congress, Society of Arts, John-  
bi.

## FURNITURE EXHIBITION.

bition of Works of Art Applied to  
n connection with the Exhibition of  
the Royal Albert Hall, is now open  
on-transferable season<sup>1</sup> ticket will be  
member of the Society on application  
ary.

## EXAMINATION IN VOCAL OR INSTRUMENTAL MUSIC.

Examination in London will be held  
lah, the Society's Examiner, at the  
e Society of Arts, 18, John-street,  
C., during the week commencing on  
1881.

## HONOURS.

ination in Honours will consist of  
is, viz., a paper to be worked, an  
similar in form to the practical  
for a First and Second-class, and a  
mination.

## FIRST AND SECOND-CLASS.

## Vocal.

for a First or Second-class Certificate  
ic will be required—

g a solo, or to take part with another  
a duet, already studied.

-note being sounded and named by  
r, the candidate to name sounds or  
successions of sounds or intervals,  
g by the Examiner.

g or sol-fa at sight passages selected  
in classical music.

## Instrumental.

for a First or Second-class Certificate  
tal Music will be required—

[1.] To play a short piece, or a portion of a  
larger work, already studied.

[2.] A key-note being sounded and named by  
the Examiner, the candidate to name sounds or  
intervals, played by the Examiner.

[3.] To play a piece or portion of a piece at  
sight.

The examination of each candidate will be  
private; no one but the Examiner and the accom-  
panyist being present, unless it be a member of  
the Society of Arts' Committee.

No list of Candidates will be published.

Full particulars can be obtained on application  
to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

## CONVERSAZIONE.

The Society's *Conversazione* was held at the South  
Kensington Museum (by permission of the Lords  
of the Committee of Council on Education), on  
Thursday, 2nd June.

The Galleries containing the Raphael Cartoons,  
the Sheepshanks Collection, the Wm. Smith Collec-  
tion of Water Colour Drawings, the Dyce and  
Forster Pictures, the Collection of Paintings lent  
by the Trustees of the late Rev. Pryce Owen, and  
"The Chantry Bequest," as well as the Courts  
and Corridors of the Ground Floors were open.  
The Reception was held in the Architectural  
Court, by Mr. F. J. BRAMWELL, F.R.S., Chairman,  
assisted by the following Vice-Presidents and  
Members of the Council:—Professor Abel, F.R.S.,  
Mr. Brudenell Carter, Mr. B. Francis Cobb, Sir  
Philip Cunliffe Owen, K.C.M.G., Mr. W. H.  
Preece, F.R.S., Mr. Robert Rawlinson, C.B., and  
Mr. Owen Roberts.

A Promenade Concert was given by the String  
Band of the Royal Engineers (Conductor—Herr  
J. R. Sawerthal), in the North Court, the follow-  
ing being the programme of music performed:—

- |                                     |                             |             |
|-------------------------------------|-----------------------------|-------------|
| 1. Overture.....                    | "Giralda" .....             | Adam.       |
| 2. Selection.....                   | "Don Giovanni" .....        | Mosart.     |
| 3. Musette .....                    | "Amors Klüsse" .....        | Morley.     |
| 4. Serenade .....                   | "Ständchen" .....           | Schubert.   |
| 5. Fantasia .....                   | "Dinorah" .....             | Meyerbeer.  |
| 6. Chor der Schaarwache .....       |                             | Gretry.     |
| 7. Selection.....                   | "Pirates of Penzance" ..... | Sullivan.   |
| 8. Spanische Tänze .....            |                             | Moszkowski. |
| (a) Moderato.....                   | (b) Bolero.....             |             |
| 9. Waltz.....                       | "La Berceuse" .....         | Waldteufel. |
| 10. La Retraite Militaire .....     |                             | Lefèvre.    |
| 11. Marche Romaine (Pius IX.) ..... |                             | Gounod.     |

Mr. Corney Grain gave an Entertainment in  
the Lecture Theatre, and Madame Frickenhaus'  
Pianoforte Recital was given in the Picture  
Gallery, the programme of the three parts of  
which was as follows:—

- |                      |       |         |
|----------------------|-------|---------|
| a. Etude, No. 3 }    | ..... | Chopin. |
| b. Scherzo, Op. 20 } | ..... |         |

- |                        |       |           |
|------------------------|-------|-----------|
| a. Trauermusik .....   |       |           |
| b. Einsame Blume ..... |       | Schumann. |
| c. Novelette, Op. 99 } | ..... |           |

- |   |              |
|---|--------------|
| a. Capriccio (for the left hand) .....  | Rheinberger. |
| b. Scherzo, from Sonata in A flat ..... | Weber.       |
| c. Tambourin .....                      | Raff.        |

The number of visitors attending the *Conver-  
sazione* was 2,710.

## EFFORTS TO IMPROVE NATIVE HUSBANDRY IN SOUTH INDIA.

By Wm. Robertson.

In May, 1880, I had the honour to read before the Society of Arts a paper on "The State of Agriculture in South India." Since then the Indian Famine Commission report has been issued, and several important papers, embracing many of the subjects dealt with in my paper, have been read before this and other societies. Of course, on such questions some differences of opinion must exist, but, on the whole, the opinions expressed agree, generally, with those I ventured to place before you. My conclusions may be summarised regarding South India as follows:—

(a.) The good land is already under tillage; any addition made to the tillage area must therefore consist of inferior soils.

(b.) Additions made to the tillage area must be at the expense of the area that produces scrub-jungle and grass, which afford the ryot—free of cost—fuel for domestic use, and grazing for his stock, which resources thereby become lessened.

(c.) The addition of large areas of poor soils to the area under tillage, increases the necessity for applying manure, while the corresponding decrease in the area yielding fuel and grazing, diminishes the ryot's means of supplying this manure.

(d.) The proportion of the occupied area, cropped annually, is considerably greater now than at any previous period, thus the benefiting influences of "fallowing" are less exercised.

(e.) Half-tilled, unmanured, arable land, bare for six months in the year, is much less able to retain and store the rainfall than the land when under scrub-jungle; the rain-water flows more quickly off the land into the beds of streams, and the irrigation sources dry up sooner in the season.

(f.) There is, generally, a great waste of irrigation water; were the water used with care, the irrigable area might be largely increased.

(g.) Famines occur during long periods of drought, when the crops cannot obtain the water they require.

(h.) The half million persons added yearly to the population of the Presidency, rely for food chiefly on crops raised on inferior soils, farmed without the aid of irrigation water, and almost without manure.

(i.) Under present conditions, famines are likely to become more frequent and more severe.

(j.) Under good husbandry—by deeper tillage, and by the use of organic manures—the soils might be made much more fertile, and the crops rendered less liable to suffer injury during a moderate drought.

(k.) The welfare of the State depends upon the condition of agriculture, even to a greater extent now than formerly, seeing that it has guaranteed to protect the people against the effects of famine.

(l.) A primitive system of husbandry, which sufficed to meet the wants of a scanty population, when there was plenty of good land available, no longer suffices, now that the demand for human food has become so great, and such a large area of poor soil has to be tilled.

Early in the present century attention was given by the State to the improvement of indigenous

varieties of cotton, but nothing on an extensive scale was attempted until about 40 years ago. The Marquis of Tweeddale was Governor of the Cotton Department was then organised, and farms were established in various parts of the Presidency. These so-called farm experiments, were mere tracks of land, fenced, and generally without any but the best land was devoted exclusively to the culture of cotton. On these farms, crops of Egyptian, and New Orleans cotton were raised from imported seed, and the seed was distributed over the Presidency; but the land was devoted chiefly to the culture of the best indigenous cotton, which, it was thought, would be improved by better culture, the liberal use of manures, the careful selection of seed for sowing, &c. These farms were under the charge of men who had been brought from England and who were supposed to possess the knowledge of the cultivation of cotton, and the treatment when undergoing preparation for the market. In connection with these farm experiments were carried on in ginning and packing, and in the export of cotton. These cotton farms were carried on in the face of many difficulties. Important experiments were carried on, and important information was collected. The Governor having been appointed, and his interest in agriculture, the partial opposition, which had existed for many years, assumed an active form, and the Cotton Department was eventually suppressed. No doubt whatever that the administration of the department was defective in several respects. But, taking into account the state of agricultural knowledge at that period, the difficulties to be overcome, and the class from whom aid and assistance have been hoped for, the experiments were as successful as in reason could be expected. It was certainly a mistake to confine the culture of the farms exclusively to cotton. Had efforts been made on a similar scale, with the same persistency, to improve generally, any improvement secured would have been acted for good on cotton culture, as thus obtained would have been in their influence. It was also a decided mistake to import largely seed of superior varieties from countries where cotton is grown on almost virgin soils, or cultivated by intelligent planters, and to attempt to introduce these kinds of cotton at once into the hands of the natives in South India, on impoverished, half-tilled, unmanured soils. Before such a system can be grown in South India there must be a very great improvement in the character of the husbandry generally. In a few favoured localities, in various parts of the country, the conditions necessary for the culture of the higher races of the cotton plant undoubtedly be secured; but the most favourable circumstances are already utilised.

However, as I have already stated, the Cotton Department effected much good. Now, in certain districts in South India, of cotton introduced and acclimated in the department, which, though not much

rior to any indigenous cotton; while be no doubt that the immense quantity cotton seed distributed over the country d much good in indigenous cotton, by ing with it.

under which the Cotton Department ssed, was that the department was not success—that its income did not meet s; as if this was the standard by which of the operations conducted were to be never can understand why in India this hould be applied only to enterprises their object the improvement of agri- ere the same standard applied to the he working of the various departments e, in determining the claim of these s for continued existence, I fear they o no better ground to exist longer than funct Cotton Department; while, in y, that great institution, the South Museum, which is doing so much for on of the British public, the equally institution at Kew, would have to be were their results judged of by this g standard. It is true that the out- successful agricultural enterprise must, , be a gain, but it does not follow that an be made to assume a money form e.

any difficulties encountered in conduct- rk of the Cotton Department, not the e suspicion with which its operations l by the ryots generally. They could e it possible that a Government, influenced only by ordinary commercial ld act, as it were, disinterestedly. In ces they not only refused the use of for the experiments, though a liberal pensation was offered, but not unfre- used to accept, for sowing, superior when offered free of all charge. They ly to believe that the sole object of t in giving attention to cotton culture, e reason for raising the rent of the land. closing of the Cotton Department, the drew from all active interference in vation, and, for some years, but little y the State in any other direction to- cultural improvement. A few isolated s were conducted here and there under ectors, notably the late Mr. John Sul- in the Coimbatore Collectorate, con- ny useful agricultural experiments, the introduction of new crops on the en constituting a portion of the Coim- rict. Amongst other crops he intro- , was a variety of wheat obtained from , which at one time was largely culti- ees hills, and, even now, is grown to there. This gentleman also introduced several crops now well established on Hills. But, generally, the experiments by collectors at this period seldom ults of a useful nature, not so much of knowledge or want of interest on collectors, but from want of leisure to periments the required attention, and equency with which they were trans- her collectorates.

ral shows have been held in various

parts of South India, with a view to the promotion of agricultural improvement. About twenty-five years ago, shows of this nature were frequently held in the different districts. At these shows prizes were offered for good specimens of agricultural stock, field produce, agricultural implements, tools, &c. The shows were held at the head-quarters of the collectorates. The prizes were numerous, but small in amount. The average cost of such a show was about £200, the whole of which was provided by Government. In the districts of South India, among a people so backward as are the rural classes there, generally, the holding of agricultural shows could not but be attended with advantage. But the shows were, at first, undoubtedly looked upon with great suspicion by the agricultural classes. The Revenue Board of the Presidency, in referring to one of these provincial shows observed, "The committee at Cuddapah had great difficulties to contend with, and experienced considerable opposition. The show, therefore, can be regarded as having effected little more than dissipated the suspicions and fears of the people." Afterwards, in referring to the results of the first series of these shows, the Board remarked, "The provincial exhibitions, generally, have been as successful as, under all circumstances, could have been expected." About three or four years later (1859), a number of provincial agricultural shows were again held in Madras, fifteen having been held in that year, at a cost of about 35,000 rupees. The results of these shows, appeared to have been considered disappointing, for the Board of Revenue, who again had the control and general management of the shows, thus wrote:—

"On the present occasion, long notice was given, and full publicity ensured. The sum placed by Government at the disposal of the local committees was ample, and liberal prizes were offered for competition. The Board regret, however, to state that, with few exceptions, the result has not been satisfactory. The novelty of the thing has, to a great extent, worn off; the preconceived idea, of the majority of the exhibitors, apparently, that the trouble of producing a specimen was in all cases deserving of reward, without reference to the character of the article, and their corresponding disappointment, the depreciating accounts of unsuccessful competitors, the fear of cholera, and, in some instances, the superstitious belief that the unfavourable seasons of late years were to some extent produced by the 'evil eye' of those to whom the produce of their labours was publicly exhibited, have combined to produce this result. The interest, however, of the spectators seems to have been unabated, and that good has resulted from the movement the Board believe. The cultivation of valuable special products has been extended, and in some cases originated—improvements in farming, in cattle breeding, and in implements, have been encouraged, and some acquaintance with the advantages of machinery afforded. Some branches of manufacture, which promise to be valuable, have been developed, especially in fibres, and it may confidently be expected that the seeds of emulation and enterprise that have been sown will bear fruit in the future."

If the results mentioned in the latter part of this quotation were really as stated, I venture to think that these provincial shows were successful, and that they ought to have been continued from year to year.

During the last 20 years, but very little has been done in holding agricultural shows. Two have

been held near the City of Madras, and one on the Nilgiris, and one or two in other districts; but none since 1874. In one district, that of Nellore, cattle shows were held for several years in succession; but these also have been discontinued. At the present time, therefore, this highly important means of improving agriculture is altogether unemployed in South India.

In England, with its highly advanced agriculture, we have in every county an agricultural association, and in many counties several district or local agricultural societies, all actively at work in promoting agricultural progress. These associations and societies in the British isles spend annually very little less than half a million pounds sterling; an expenditure which, I think, can be justified on strictly commercial principles, and yet, according to the present Indian official view, such an expenditure would be considered unjustifiable. I am strongly of opinion that agricultural shows should be held annually in every district of South India. The cost would be but trifling compared with the vast revenue the land yields the State, and I am confident that eventually satisfactory results would be secured. For a time we must be content to sow, feeling assured that, if proper means are taken, a harvest of good results will certainly follow. Agriculturists are slow everywhere in adopting improvements. It is unfortunate that, in dealing with the great question of agricultural reform in India, narrow-minded, unintelligent views have been allowed to crush the germs of reform. The matter must be viewed from the same standpoint as ordinary educational efforts. If the expenditure of £100,000 a year on literary education in South India is justifiable, surely the expenditure of a few thousand pounds annually over that country, in promoting the material interest of the classes amongst whom we are so anxious to create M.A.'s and B.A.'s is, to say the least, equally justifiable. But, then, our land administrators are "classical scholars," not agriculturists, and their panacea for the deplorable state of the agricultural classes—and, let it be remembered, India is essentially an agricultural country—is education in Greek and Latin.

When Sir William Denison became Governor of Madras, attention was again directed to agricultural improvement, and this was kept up until Lord Napier, who succeeded Sir William Denison, ceased to be the Governor of the Presidency. A large number of agricultural implements and machines were then purchased in this country, but, when they arrived in India, it was found that they could not be worked under suitable conditions, Government then having no suitable land under its direct control on which the machines could be worked. The necessity for testing these machines, &c., under proper superintendence, suggested to the authorities in 1865, the propriety of establishing a Government farm; and a piece of land of about 300 acres, situated about six miles to the south of Madras, which was then covered by a prickly-pear jungle, was selected as the site of the farm. The selection was made because the land was the property of Government, and because the medical authorities had declared that it was absolutely necessary to clear the land, as in its then state it was the cause of much fever in the neighbouring town of

Saidapet. A committee of Government was appointed to manage the farm operations were confined to clearing of land, sufficient to afford opportunities field implements, chiefly light ploughs. years after opening the farm, but little beyond clearing the prickly-pear jun out the land in fields, making roads, & cattle-sheds. The committee got together useful varieties of farm stock, and conducted small experiments in growing new crops; their attention was chiefly confined to those of which they imported several useful kinds this period of the farm's existence, the object of its conductors was simply to show the value of certain implements of a suitable kind which worked with success by the cattle of the country. They also gave attention to water-lifting, and they purchased and erected several kinds for experimental trials.

In 1871, this committee was abolished, and general control of the farm was given to the Presidency Board of Revenue. It was proposed that the farm at Saidapet should be a central experimental station, with branch experimental stations in each district of the Presidency, the whole to be conducted by a small staff then organised, with headquarters at Saidapet. The objects to be kept in view by the Government were specified by Government to be as follows:

- (1.) To ascertain, by experiment, the best system of rotation in crops in this country.
- (2.) To introduce the system of rearing crops, in lieu of fallow, without artificial manures.
- (3.) To introduce new crops.
- (4.) To provide new kinds of seed for the crops now cultivated.
- (5.) To make experiments in the use of the cultivation of crops now termed "fodder" and for raising grasses and other crops as fodder.
- (6.) To make experiments in the use of other manures, mineral and animal.
- (7.) To introduce new and improved methods of rural labour.
- (8.) To improve the working of horses, and other varieties of live stock in the country.

These objects have been steadily kept in view by the management of the department, and, very limited means permitted, or as the authorities would allow.

The first difficulty that presents itself in attempting to carry out the scheme is the absence of qualified natives, who alone placed in charge of the district station. To overcome this difficulty, Government authorised the establishment, at Saidapet, of a number of students were to be trained there, for employment as superintendents of these stations. The youths were to become qualified for the duties merely by taking part in the ordinary operations of the farm. Though liberal salaries were offered, and promises were held out of employment on liberal salaries, no youths, of the stamp required, could be found to join this apprentice class. The fact that the culture was at that time known to be generally, it was estimated a pursuit of the unintelligent portion of the com-

formed of the sons of subordinate officials, who duly appreciated the high stipends (month) offered, but it was soon ascertained that mere field-training would never fit for forming the class to hold the position of superintendents of experiments. After a very full trial, the fact ascertained—a fact well known before to those with the subject—that in order to produce native superintendents for the experimental stations, it was absolutely necessary to secure well educated youths, and to give them a prolonged training of a systematic character.

In this view, the Revenue Board of India concurred, as the following extract from their published proceedings shows:—“The want of a systematic instruction in agriculture is bearing on it is given at the Saidapet experimental superintendents for the experimental stations, cannot be trained

without superintendents trained in the experimental farms will be of little or no use. The means for giving such a training, the students, and the opportunities for what is taught, and the funds, are all wanting. The good effects of the instruction will be felt by a few superintendents of Government farms, as in England, America, France, and

as a scene of systematic instruction open at the Saidapet farm will be infinitely more public than it is at present.”

After a great expenditure of time in discussing the question, that a report was obtained for the establishment of an agricultural college, on a small scale, in which youths could be trained for the purpose, as superintendents of district experiments, and agricultural instructors; employment, &c. A comprehensive plan was organised, and its details extensively discussed in the form of a prospectus. Though the plan was originated in view to train a few superintendents, &c., no inducements were held out of State employment to those who passed successfully through the course.

Indeed, there was a nervous anxiety that every candidate should clearly show that, in qualifying as an agriculturist, he would thereby establish no claim on Government. In connection with the institution, 24 bursaries were established, at about £15 a year, and tenable for the first three years of the three years of training. Bursaries could only be got and really industrious students, after six months' attendance at the college, and who completed their whole course of training to the standard of progress laid down. A sum of marks was to be gained at each monthly or more examinations of each year, the evidence of a thorough practical acquaintance with the working of ploughs and implements was insisted on.

Sufficient time had elapsed to allow of the publication of the prospectus, and discussion in the native press of the objects of the new institution, applications from

would-be candidates began to be received in considerable numbers, and from nearly all parts of India. No candidate was accepted who had not qualified in the educational standard prescribed for ordinary State employment, or for proceeding to a University degree, or who failed to pass the special (equally difficult) entrance examination of the college. All candidates had to produce medical certificates of physical fitness for active employment, certificates of character, &c., and each candidate selected was between the ages of 18 and 24.

Notwithstanding the previous repeated failures in filling the apprentice classes, when such substantial advantages were offered, there was no difficulty now in securing any number of qualified, educated youths. The institution began work in 1876, with a first class, in temporary sheds. The erection of commodious but unpretentious buildings was sanctioned, in which to carry on the work of the institution. The permanent accommodation was to consist of lecture-rooms, class-rooms, a reading-room, and a library; and separate buildings were to provide accommodation for a veterinary hospital and a chemical laboratory; while, in addition to the farm, botanical grounds were to be established; but only the chemical laboratory has yet been erected. The nature of the training afforded by the institution, will be gathered from the following extracts from the college prospectus:—

“The instruction given in the institution will embrace a thorough study of agriculture, and of such portions of chemistry, geology, zoology, botany, and the veterinary art as bear on the theory and practice of agriculture. In addition to these special subjects, the following will also receive attention:—Farm book-keeping, land surveying, mensuration, and drawing. The instruction will be given by means of lectures, class-room discussions, and field classes.

“During the portion of the day set apart for practical instruction in farming out of doors, every student will be expected to take part in whatever work is going forward on the farm; compliance with this regulation will be strictly enforced. Each student will be expected to make himself acquainted with all the operations daily performed on the farm, and will be required to keep a journal or diary of the same.”

In 1878, a second class was formed, and applications for admission into it were even more numerous than they were for admission into the first class. That there was a widespread demand for agricultural instruction was amply evident.

In reviewing the work of the institution at this period, after it had been at work for nearly three years, the Government of the Presidency, in a published order, stated, “the progress and working of the institution have, on the whole, been very satisfactory.”

A change of policy, however, took place at about this time in the treatment of the institution, partly under the influence of the general State policy of reduction of expenditure, from which that department suffered. And of the twenty-four bursaries attached to the institution, nine were then suppressed, and these were afterwards reduced to five only in a class; while the value of the bursaries was reduced from about £12 to £8 per annum. The entire saving to the State by these reductions would amount to only about £100 a-year; but the effect, combined with other causes, was highly injurious to the institu-

tion, for, when it was again attempted to form a new class, only seven eligible candidates were secured.

The practice of paying stipends, or bursaries, to youths undergoing special training, is almost universal in India, in the Medical, Forest, Educational, and Engineering Departments. Very few students from the agricultural districts can afford the expense of journeys, frequently long, and the cost of maintenance away from their homes, during a three years' college course. The provision of bursaries to aid indigent able students, is as necessary, to say the least, in South India, as in Scotland, Ireland, or England. A time may, it is hoped, arrive when agricultural education in India may not require to be aided in this way; but as long as such aid is necessary in every civilised country, it surely was premature to withdraw such aid from the but recently started agricultural institution in Madras.

Only one class of students has completed the full period of training in the Madras College. Of these young men, the majority are filling agricultural situations, and generally with credit; eight of them are employed as agricultural instructors in the Bombay Presidency; but, in Madras, none of the graduates of the college have yet been employed by Government, though there were several well fitted, after undergoing a little special training for the posts of agricultural instructors, and for superintendents of experimental stations, the establishment of which has been deferred so long from the impracticability of previously getting qualified native superintendents.

(To be continued.)

## MISCELLANEOUS.

### XANTHORRHOEA RESINS.

A paper was read by Mr. J. M. Maisch on these resins, at the Philadelphia Pharmaceutical meeting of April 19th last, which is reported in the *American Journal of Pharmacy*. The author, after having seen a resin exhibited as a new Australian product, under the name of Gum acroides, discovered that the supposed new commercial article had been known in the United States for upwards of 26 years, and was, in fact, identical with Botany Bay resin.

"The genus *Xanthorrhoea* belongs to the natural order of *Liliaceae*, is confined to Australia, and consists of shrubby, or arborescent plants, somewhat palm-like in appearance, and having at the summit dense tufts of very long, wiry, narrow, two-edged, or somewhat triangular, leaves, resembling grass leaves; hence the name *grass-trees*, by which the species are known in Australia. The leaves are used as fodder for cattle, and the somewhat sheathing base of the inner leaves and the buds are edible, and form, particularly when roasted, an agreeable article of food. From the centre of the leaf tuft, there rises a long cylindrical scape, which terminates with a long spike of small white flowers, situated in the axils of the imbricate bracts, and producing triangular three-celled capsules, containing flattish, hard, black seeds.

"R. Brown (1801) described seven species, viz., *X. eriothra*, *australis*, *acutula*, *media*, *minor*, *bracteata*, and *pubes*. The two first-named species are arborescent, while the third and fourth have short stems, that of *X. acutula* being about 4 feet high, and is said to some-

times attain a diameter of 1 foot, and that is probably more than a century old, owing to its age. The last three species named before are said the stems remain buried in the soil or near the ground.

"All the species abound in a resinous juice, exposure, hardens, and as obtained from the species, undoubtedly differs in appearance and composition. Guibourt distinguishes three resins—one yellow, one brown, and one red. The coloured resin is still ascribed by some to *Acutula*, but Drummond (1840) pointed out arborescent species, probably *X. eriothra*, is called 'black boy,' and the Pharmaceutical Victoria state that *X. australis* (which is said yields a large quantity of a brilliant ruby resin. On the other hand, the botanist in the yellow resin to *X. acutula* and some of the last named is the *X. resinosa* of Persoon. *Xanthorrhoea resinifera* is quoted as a synonyme 'Supplement.' The name scaroid resin is plain. The different xanthorrhoea resins described more especially in regard to the papers by Mr. Redford, as a polishing material, *American Journal of Pharmacy*, 1863, p. 43 by Mr. P. L. Simmonds, in the same journal, p. 226 to 228, and in 1866, p. 463 to 468, last quoted refer chiefly to the use of the manufacture of illuminating gas. The resin is obtained as natural exudations, the portions of the plant producing them is at least, apparently in great abundance; also found covering the base of the leaves secreted in such quantity in the woody stem crushing the latter, it may be sifted from the extent of a hundredweight per day labourer.

"The scaroid resin, which was first sold by Governor Phillip ('Voyage to Botany' with its tears and in large masses usually, of its brittleness, broken into irregular pieces intermixed with portions of wood, stalks and when fractured has a speckled or granular appearance. The pure resin is reddish yellow; the article is externally brownish yellow, as opaque and of a pure yellow colour, resin gamboge, but always much lighter. The description by Guibourt agrees with the resin sold here; but since the resin is deemed authors as being of a deeper yellow than is evident that it must be sometimes of different species. Triturated with water form an emulsion. When fresh it is analogous to that of poplar buds, but agreeable (Guibourt); the odour appears very nearly that of benzoin mixed with storax. By age the odour becomes gradually disappears, but it is always powdery or by fusion. The resin dissolves leaving only 0.07 of a gum insoluble in alcohol, analogous to balsorin. When heated it gives vapours, condensing into brilliant small crystals. Laugier regarded as benzoic acid, but W. (1848) found to consist largely of cinnamic acid.

"The brown resin has a more balsamic odour preceding; the tears are roundish, extra brown, and resembling dragon's blood; the resin is shining, glass-like, and in this state perfectly transparent, and of a hyacinthine colour. It is completely soluble in alcohol, and a volatile oil, rendering it viscous and somewhat solid.

"The red resin is in distinct tears of a red, and sometimes externally bright red resin glass-like; thin splinters are transparent red; it is completely soluble in alcohol, intermixtures excepted, and the balsamic odour always apparent on heating.

g the composition of the xanthorrhoea quotes the analysis of Lichtenstein (1799), agier, Wiedemann (1825), Trommsdorff (1848). Heated with manganic binshuric acid, acaroid resin evolves the odour almonds, and by the action of nitric acid it proportion of carbazotic (picric) acid with soic and oxalic acid (Stenhouse). Trommsdorff volatile oil to be colourless, fragrant, and aromatic taste. The resin is soluble in the alkalies and alkaline earths. On dry such carbolic acid is obtained, with a small light oil, but, according to Sommer, no. In 1866, Hlasiwetz and Barth ascertained resin on being treated with fusing potassa quantities of paraoxybenzoic acid, and from pur of the ethereal solution a little resorcin was obtained, together with the double protocatechuic and paraoxybenzoic acids  $\equiv$   $\text{I}_2\text{O}$ , which had been previously obtained

ferent xanthorrhoea resins were found by 877) to be incompletely soluble in chloroform, but to dissolve completely in alcohol, acquiring a brown-black colour with ferric solution of the acaroid resin is yellow, with lead acetate a precipitate, while the other two resins are red, that of *X. arborescens* produces with the same reagent the chloroformic solution of the latter is of the former colourless.

xanthorrhoea resins have been repeatedly possessing some value in perfumery; but to be inferior for this purpose to benzoin, the balsams of Peru and Tolu. Their properties appear to be likewise not well known, early as 1796, experiments were made on, for the purpose of learning their properties (*Boston Journal*, x., p. 94) employed it as tincture, with opium, in phthisis, and it recommended in chronic catarrhs. A tincture, mixed with milk or a mucilaginous oen recommended to be made of equal parts resin and alcohol."

## THE AUSTRALIAN DESERT.

the geological and zoological features of parts of South Australia, by Mr. E. B. B. been lately issued, from which the following *Colonies and India*, showing that there been considerable misapprehension as to the great Australian Desert":—

Gums to Manuaukaninna the country stony tablelands, alternating with alluvial borders of the tablelands are generally the central portions; thus, when seen from they assume the appearance of low flat-topped plain is intersected by one or more water for the greater part of the year, or at any up into a few waterholes. The water a general westerly flow, and after a certain run out altogether or expand into a, as it is called, a lake; one or two of the side to empty into Lake Eyre. When the sets in, or even after a heavy shower, they and, overflowing their banks, spread over flats, forming the so-called 'lakes.' The gradually drains away, leaving the flats. Some, however, of the flats, being situated level than the others, have water over them round, as, for example, Lake Harry. rainfall has been nil, or, at least, very

small, for two or three successive seasons, as is often the case, these last-named lakes soon grow salt and unfit for drinking. This is explained by the fact that the flood-waters wash out from the rocks and hold in solution a large percentage of the chlorides, carbonates, and sulphates of sodium, calcium, and magnesium. Accordingly, when the water is spread out over a large surface, as on the flood-flats, evaporation takes place very rapidly, until concentration occurs to such a degree that the water is unfit for use. When, however, a new flood comes down or a heavy rain occurs, the lakes assume their pristine freshness. The most interesting feature of the tableland country to a geologist is the enormous effect of denudation. Every flood brings down a vast amount of detritus, and deposits it over the plains. In some places the alluvial deposits attain a thickness of 50 or 60 feet. On the tablelands the destructive effects of denudation are seen better still. One cannot but be surprised when one looks over the immense heaps of water-worn stones lying everywhere, and forming a talus to every cliff, and reflects upon the apparently small causes that have been able to produce such large results. One is necessarily impressed with the vast amount of time it must have taken.

"On the tablelands vegetation is comparatively poor, consisting of stunted shrubs and trees. But, desolate as it appears, after rain grass springs up with amazing rapidity, and what a short time before was a desert of stones, become clothed in a garment of brilliant green. It is, however, on the rich alluvial plains that the vegetation is the most luxuriant and the best pasture found. North of Manuaukaninna the appearance of the country changes completely. The stony tablelands disappear, and in their place low ridges of dazzling white sandhills stretch away for hundreds of miles to the north and west. Here commences what has been called the Central Desert of Australia. The term desert, however, should be used with caution. No one seeing the sandhill country after a heavy rain would venture to call it a desert. It must be admitted, however, that during the long periods of drought it is indeed but little more than a second edition of Sahara. It is owing to the great difference in the appearance of the country in the wet season and its aspect in the dry season, that discrepancies have arisen between the reports of persons who have explored the region. Some have described the interior as a veritable desert, and others as a magnificent country, peculiarly adapted to pasture.

"The sandhills have a general north and south trend. A peculiarity worthy of note, and which will be explained further on, is that the western sides are invariably sloping and the eastern sides abrupt. Between the sandhills are flood-flats, similar to those we have described as alternating with the stony tablelands, and, like the latter, are periodically flooded by the overflowing of the creeks that wind through them. The flood-water is generally not of local origin, as in the tableland country, but is the result of heavy rains in the tropics far to the north. The surplus flood-water from the tropics backs down the Cooper, Diamantina, and the network of watercourses which connect them, and ramify through the country, and slowly fills the lakes and flood-flats. This happens, to a certain extent, every year. The Cooper and other creeks are then said to 'run.' This overflow of tropical rains reaches annually as far down the Cooper as Coongie, but it is only an exceptional flood that causes the Cooper to run below Coongie and fill the large lakes between there and Manuaukaninna—i.e., Lake Hope, Lake Perigundi, and Lake McKinlay. As a matter of course, in seasons of prolonged drought, the above-mentioned lakes become salt. Occasionally heavy local rains freshen the water of the lakes and fill the waterholes in the creeks, but never, as far as I am able to ascertain, cause a flood. The alluvial deposits necessarily differ in character from those of the tableland

country. The former are composed for the most part of a red gritty clay, while the latter are stiff blue marls. These two clays may be said, to a certain extent, to be characteristic of the two regions. Where the red gritty clay is found, the old palaeozoic rocks may be looked for. The blue freshwater marl is only met with in the sandhill country. The explanation of this difference is at once apparent when the nature of the rocks from whence the alluvium is derived is examined. On the one hand it is derived from schistose, slaty and porphyritic rocks, with veins of black oxide of iron, which last when washed out by the water oxidises, forming the red oxide of iron which gives the alluvium its red colour; on the other hand it is derived from the tertiary sand and limestones, and mixed with a large amount of decaying vegetation. We have spoken of the arrangement of the sandhills in parallel ridges having a north and south trend, and also of the sloping character of the western side and the abruptness of the eastern side. These facts will serve to throw some light upon the origin of sandhills. After any windy day, if we look at a stretch of land where the wind has had free access, it will be found that the sand is thrown into series of small ridges or ripples, whose long axes are transverse to the direction from which the wind blows. On examining them closer it will be seen that the side towards the wind is sloping, and the opposite side abrupt. Here again, we have in miniature the whole sandhill country. Now, the same cause that made the land ripples has made the hills, and that is the wind. In the one case it took a day, in the other it has taken many centuries, to produce the result. The prevailing winds throughout the region are westerly, and, as we should expect, the sandhills tend north and south. And, again, the sloping side of the sandhills face towards the wind. The sandhills of the country, in fact, indicate the direction of the prevailing wind. No fact is impressed more strongly upon a geologist than this—that it is with comparatively small means that nature produces the greatest results. Whether it is the upheaval of the Alps, or the subsidence of the coral basin of the Pacific, the levelling of mountain ranges or the filling-in of ocean basins, in all apparently small causes produce the result—in all the same grand impassive uniformity is displayed."

#### FAURE'S SECONDARY BATTERY.

Sir William Thomson, F.R.S., has written the following letter to the *Times*, containing the results of his experiments with Mons. Faure's battery, described in the *Journal* of May 20th (p. 576):—

The marvellous "box of electricity" described in a letter to you, which was published in the *Times* of May 16th, has been subjected to a variety of trials and measurements in my laboratory for three weeks, and I think it may interest your readers to learn that the results show your correspondent to have been by no means too enthusiastic as to its great practical value. I am continuing my experiments to learn the behaviour of the Faure battery in varied circumstances, and to do what I can towards finding the best way of arranging it for the different kinds of service to which it is to be applied. At the request of the Conseil d'Administration of the Société de la Force et la Lumière, I have gladly undertaken this work, because the subject is one in which I feel intensely interested, seeing in it a realisation of the most ardently and unceasingly felt scientific aspiration of my life—an aspiration which I scarcely dared to expect or to hope to live to see realised.

The problem of converting energy into a preservable and storable form, and of laying it up in store conveniently for allowing it to be used at any time when wanted, is one of the most interesting and important in the whole range of science. It is solved on a small

scale in winding up a watch, in drawing compressing air into the receiver of an air-Whitehead torpedo, in winding up the watch or other machine driven by weight pumping up water to a height by a windmill, as in Sir William Armstrong's hydraulic pump for the purpose of using it afterwards by a waterwheel or water pressure. It is solved on a large scale by the use of burning fuel to smelt zinc, to be afterwards to give electric light or to drive an electric engine, by becoming, as it were, unsmelted in battery. Ever since Joule, 40 years ago, for the thermodynamic theory of the voltaic battery, the idea of applying the electro-magnetic engine, the idea of applying to work the battery backwards, and thus converting chemical energy to the materials, so that they act voltaically, and again and again, has been in science. But with all ordinary forms of voltaic the realisation of the idea to any purpose seems so distant. By Planté's admirable discovery of lead and peroxide of lead voltaic battery, all your correspondent, an important advance towards the desired object was made 20 years ago; and in the Faure's improvement practical fruition is attained.

The "million of foot pounds" kept in the Faure's 72 hours' journey from Paris to Glasgow is an exaggeration. One of the four cells, after charged, was recharged again by its own battery, and then left to itself absolutely for ten days. After that it yielded to me 2 pounds (or a little more than a quarter of a pound) of This not only confirms M. Reynier's measurement of the faith of which your correspondent's statement is made; it seems further to show that the waste of energy by time is not great, and that for day at all events, it may not be of practical moment, however, is a question which can only be answered by observations and measurements carried on longer time than I have hitherto had for in the Faure battery. I have already ascertained regarding its qualities to make it quite certain solves the problem of storing electric energy, and on a scale useful for many important applications. It has already had in this an interesting application, of the smallest in dynamical energy used, but not of the same respect to beneficence, of all that may be expected. A few days ago my colleague, Professor Buchanan, carried away from my laboratory lead cells (weighing about 18 lb.) in his car by it ignited the thick platinum wire of an *écrouseur*, and bloodlessly removed a navoid from the tongue of a young boy in about a minute. The operation would have occupied over ten minutes performed by the ordinary chain *écrouseur*. I have been had the Faure cell not been available in the circumstances the surgical electric his paraphernalia of voltaic battery to be set hand, would not have been practically admissible.

The largest useful application waiting for the Faure battery—and it is to be hoped that the minimum of time will be allowed to pass before the battery is supplied for this application—is to use electric light what a water cistern in a house is an inconsistent water supply. A little battery of the boxes described by your correspondent gives the incandescence in Swan or Edison lamps to the extent of 100 candles for six hours, without perceptible diminution of brilliancy. Thus, instead of needing a gas-engine or steam-engine to work as long as the light is wanted, with the light failing at any moment through the failure of a belt—an accident of too frequent occurrence in any other breakdown or stoppage of the engine—and instead of the wasteful inactivity of the hours of day or night when it

## HENRY COLE ON TONIC SOL-FA.

called 'The Village Choir,' and if you want to know what village choirs were fifty years ago look at that picture. Somebody said it was a Protestant version of the Gregorian chant, but it will give you an idea of how music was cultivated in our churches at that time. There was no Sacred Harmonic Society, which came to this hall, and has gone. Exeter-hall was not even built then. There was no such great organisations for public singing as now exists. The Tonic Sol-fa system, although invented, was not heard of publicly. In 1871, however, vocal music in elementary schools was introduced into the Code—you know what the Code is, some of you; at least, I hope you do—it was introduced into the Code by Mr. Forster, to whom the nation mainly owes the introduction of national education. He introduced those words, 'vocal music,' into the Education Code of 1871; but before him, more than twenty years before, Dr. Kay (afterwards Sir J. Kay-Shuttleworth) had taken up the matter as far as the teachers' certificates were concerned, and Dr. Hullah even then looked after the music, and the teachers were credited with musical honours if they deserved them. Now—you will hardly believe it, those who do not know the mystery of the thing—the teachers get no credit for music at all in their certificates. You, the taxpayers, vote through your representatives £138,000 a year for bad singing—I will not call it music—and yet the teacher who has to impart this knowledge is not recognised as knowing anything about it. After these words 'vocal music' were brought into the Code, Lord Sandon—Heaven knows why—took them out and put in 'singing by ear.' In a fit of desire for popularity he reduced 'vocal music' to 'singing by ear.' Lord George Hamilton succeeded him, and he restored the words 'vocal music' and kept 'singing' also. It was ruled—'If you can pass in the Tonic Sol-fa method you can have the 1s. for vocal music, but if you only sing by ear you shall only have half the grant you get for vocal music.' Now, there is a mystery about the next change which 'no fellow can understand.' Mr. Mundella, whose zeal for education no one can doubt, immediately on coming to power, expunged 'vocal music' again. The teachers are still examined in music, and very well examined by Dr. Hullah, but they get no credit for it, and the managers of schools are told nothing about it in the certificates—the knowledge of music is not recorded in the certificate at all. Dr. Kay, who was the organiser of our national education, was the man who put it in; but who persuaded my Lords to put it out, is a mystery which nobody can fathom. Now let me speak briefly about our various academies for musical education. First we have the Royal Academy of Music, which at first led a struggling life, but by putting its shoulder to the wheel it has got out of difficulty, and is now a very flourishing institution, with its £13,000 a year. Since the Royal Academy was established, there has been a National Training School of Music established by the Society of Arts, which is doing its work fairly well, but both these institutions are bound to begin with the Tonic Sol-fa method, and to use the College for their purpose. Whilst the Tonic Sol-fa system was marching on in triumphant progress, every other system seemed on the whole to be going back. They had 29,000 schools that might be taught the Tonic Sol-fa method. They had only 1,300 taught by the Hullah, or the old notation, or the movable Doh, or anything else, but the Tonic Sol-fa, as they heard from the report, had more than 4,000 teachers, and before it had done its work in England it must get up to that 30,000, and it would do so. It is the easiest and most scientific system to begin with; it leads easily to the old notation. It is supported by such authorities as Professor Macfarren, Dr. Sullivan, Dr. Stainer, and, in fact, by every musician who will trouble himself to understand it. It will greatly aid the work of the Society of Arts in the national cultivation of music. May it prosper!"

## CORRESPONDENCE.

## MANUFACTURES, TRADE, AND PROGRESS OF ENGLAND.

When the founders of the Society of Arts established our Society, above a hundred years ago, for the encouragement of Arts, Manufactures, and Commerce, they did so to provide for the growing wants of our internal development, and also of our rising colonial empire. That design was so well laid, and has been so successfully carried on, that we are still actively engaged in its prosecution.

In that period, and particularly of later time, our external trade, on which the maintenance of our population chiefly depends, has acquired enormous proportions, but it is subjected to a most keen competition. Indeed the world is under new conditions. The provinces of America, which at our foundation may have had a million of people, showed at the census of last year above sixty millions of our English speaking men in the United States. They are consumers, it is true, of our manufactures, but still more active competitors after our own ways. Then, too, Europe is ever ready to compete with us.

Concurrently with the existence of our own Society, there have been established, partly by ourselves, many valuable institutions for the advancement of industry, not only Chambers of Commerce, but others, such as the Iron and Steel Institute, for technical improvement. Our own means and strength do not allow us to do the whole of this work, but only to co-operate in it, and they do not enable us to take charge of the general relations of our industry abroad.

At this time, as we deeply feel, we are being driven out of many a country by our American and foreign rivals, and, in some cases, the capital for these operations is obtained in our own market. Thus an American, a Belgian, or a Frenchman obtains the concession of some railway or public works, he places the securities in this country, and with the proceeds he obtains the iron, machinery, and plant from abroad, displacing us.

This is only one class of numerous operations illustrative of what is now going on, chiefly because there is no organisation of our industry, and not even a Ministry to look after our commerce abroad. Free trade does not mean free neglect of trade. To enter into the subject to any extent would take up great space, and only enforce facts, which come home to the bosom of every manufacturer.

Surely the time has come when some action, perhaps by the instrumentality of our Society, should take place, and when the Chambers of Commerce, the trade associations, and the individual manufacturers, miners, or merchants and shipowners should bestir themselves in convention and in concert to provide for their own and the national interests at home, in the colonies, in India, in America, and abroad, where, in many cases, some small care and assistance would preserve what is being wrested from us, or would open new markets for our products.

HYDE CLARKE.

## GENERAL NOTES.

## The International Medical and Sanitary Exhibition.

—It is announced that the whole of the floor space for this Exhibition will be allotted this week, with the exception of a portion which the committee have decided to set apart for exhibiting the work of journeymen plumbers. Under special regulations this work will be exhibited free of charge, and it will include the specimens of workmanship produced by the competition for the prizes in connection with the lectures on plumbing now being delivered in the room of the Society

of Arts. Plumbers wishing to exhibit should apply for particulars to Mr. Mark Judg Museum of Hygiene, University College, Certificates of merit will be awarded. H.R. Edinburgh has consented to become the patron.

## MEETINGS FOR THE ENSUING

MONDAY, JUNE 13TH...Royal Geographical, Univ. Burlington-gardens, W., 8½ p.m. 1. Baber, "A Journey of Exploration Szechuen."

TUESDAY, JUNE 14TH...National Health Society of the Society of Arts, 7.30 p.m. Hellyer, "The Science and Art of San (Lecture III.)

Medical and Chirurgical, 53, Berners street, W., 8½ p.m.

Photographic, 5A, Pall-mall East, S.W. Anthropological Institute, 4, St. Mark 8 p.m. 1. Mr. J. Park Harrison, "Ex and French Photographs." 2. ## OF THE SOCIETY OF ARTS.

No. 1,491. Vol. XXIX.

RIDAY, JUNE 17, 1881.

*cases for the Society should be addressed to the Secretary  
John-street, Adelphi, London, W.C.*

## NOTICES.

## ANNUAL GENERAL MEETING.

I hereby give notice that the One-hundred and Twenty-seventh Annual General Meeting, for the purpose of receiving the Council's statement of receipts, and expenditure during the past year, and for the election of officers and new members, will be held, in accordance with the bye-laws, on Wednesday, the 29th of June, at 4 o'clock.

I think it well to call the special Members to the above notice, and to hope that Members may find it convenient to attend, and receive the report of the work of the Session.

(By Order of the Council)

H. TRUMAN WOOD,

Secretary.

## ALBERT MEDAL.

The Council of the Society of Arts have awarded the Albert Medal of the Society of the present year to Wilhelm Hofmann, M.D., LL.D., Professor of Chemistry in the University of Berlin, for "eminent services rendered to the arts by his investigations in organic chemistry and for his successful labours in the cultivation of chemical education and research in England."

## MEDALS.

I hereby have awarded the Society's Silver Medal to the following readers of papers during 1880-81:—

ALEXANDER GRAHAM BELL, for his paper "Photophones."

EDWARDS, for his paper on "Signalling by Sound."

DR. SCHENCK, for his paper on "The Railway, and the Transmission of Power by Electricity."

HON. SIR HENRY BARTLE EDWARD FREER, Bt., G.C.S.I., D.C.L., LL.D., for his paper "Industrial Products of South Africa."

To J. Y. BUCHANAN, F.R.S.E., F.C.S., for his paper on "Deep Sea Investigation, and the Apparatus used in it."

To Professor JOHN PERRY, for his paper on "The Future Development of Electrical Appliances."

To Sir RICHARD TEMPLE, Bart., G.C.S.I., C.I.E., D.C.L., for his paper on "Forest Conservancy in India."

To J. M. MACLEAN, for his paper on "The Results of British Rule in India."

A vote of thanks was given to W. H. Preece (Member of Council), for his paper on "Recent Advances in Electric Lighting."

## DOMESTIC ECONOMY CONGRESS.

The Domestic Economy Congress in connection with the Society of Arts will be held during the week from Monday, 20th June, to Saturday, 25th June. On Monday evening there will be a *Conversazione* and Musical Promenade in the Royal Albert-hall and Conservatory of the Royal Horticultural Society at 8 p.m. The meetings for the readings of papers and discussion will commence on Tuesday, and will be held in the Great Room of the Society on Tuesday, Friday, and Saturday, at 11 a.m., and on Wednesday and Friday evening, at 7 p.m. The meetings Wednesday morning and on Thursday will be held at the Royal Albert Hall.

Mrs. Buckton's lecture at the Royal Albert Hall will be repeated, by special desire of H.R.H. the Princess Christian of Schleswig-Holstein, on Thursday, June 23, at 4 p.m.

## ART FURNITURE EXHIBITION.

The Exhibition of Works of Art Applied to Furniture, in connection with the Exhibition of Fine Arts at the Royal Albert Hall, is now open daily. A non-transferable season ticket will be sent to any member of the Society on application to the Secretary.

## PROCEEDINGS OF THE SOCIETY.

EFFORTS TO IMPROVE NATIVE  
HUSBANDRY IN SOUTH INDIA.

By Wm. Robertson.

(Continued from p. 620.)

In Madras, the Educational Department is now beginning to give attention to agricultural instruction, the subject being now taught in several of the rural schools; but nothing of a comprehensive nature can be done in this way, until qualified agricultural teachers are available. And men can become so qualified only by undergoing training in the Madras Agricultural College, which, at present, is the only institution of the kind in the whole of India, and which, I venture to believe, is as fully deserving of State support as any other technical institution in the country.

I never could understand the nervous fear that appears to exist in some quarters, lest students of the college should look to State employment as affording a career in after life. The State employs, in the administration of its vast landed estate, thousands of officials of all grades, who are totally without any agricultural education. Many of these officials are employed solely in valuing the land for rent, in collecting agricultural statistics, and in many other ways connected with agriculture. Surely there can be nothing wrong in any agricultural student looking forward to employment in any of these capacities, provided he possesses, in addition to his agricultural knowledge, the qualifications all must possess who seek for such employment. I should have thought that, for the performance of agricultural duties, preference would be given to men who possess a knowledge of agriculture; but so far, graduates of the Agricultural College have encountered nothing but difficulties in seeking for State employment where a knowledge of agriculture seems essential. From what I can gather, it appears that the obstacles are put in their way chiefly by the officials of the inferior classes, who do not like the idea of better educated men than themselves getting admission into their ranks.

The Agricultural College has been organised as the central institution for agricultural training in the Presidency of Madras, and it was intended only to afford higher agricultural education. It was proposed that elementary instruction in agriculture should be afforded in the high school of each district with which the branch experimental stations were to be connected, but, as yet, none of these agricultural classes or stations have been established. The college suffers from the absence of these classes, which were intended to be its main feeders; while the course of training in it has been prolonged, from the necessity of the institution undertaking elementary as well as more advanced instruction.

Youths of the ordinary ryot class, the sons of small occupiers, will, in the agricultural classes, at the high schools and middle-class schools in the districts, meet with such facilities for gaining a knowledge of the principles of agriculture as appear suited to their requirements. The sons of ryots of the better class, and of small zemindars, with others who desire a more complete agricultural education, will, it is proposed, pass from the local agricultural instruction classes to the college at Saidapet.

I have dwelt at considerable length, and in much detail, on the subject of establishing the Agricultural College at Madras, because I am anxious that the facts should be thoroughly known and appreciated. The experiment is one of the utmost importance in India, and it should receive fair treatment. Should any erroneous conclusions be formed regarding it, agricultural education, so much needed in that country, may be retarded for years. There are always a number of persons ready to cry out failure when anything new is being tried, and already there are persons glorying in the fact, as they assume it to be, that the college has not been a success, as if it was yet possible to form any definite conclusions on an experiment of such a nature, and conducted under so many difficulties. These persons assert that the bursaries drew the students, and that, when the bursaries

were done away with, the attractive persons, however, altogether (knowingly) misstate the facts. I undoubtedly, of much benefit to enabling them to meet the heavy frequently long journeys to and college and their homes at the beginning of each session, and, indeed, also personal expenses of the student many of the students must have more on travelling charges alone than the entire amount in bursaries, or scholarships. originally given was only such as necessary. It could in no sense be an attraction sufficient to bring students of miles from their homes. They came from places more than 200 miles from the college, several from remote parts of the Presidency, to undergo hard training of a previously unknown kind for the Agricultural College, more especially no prospect held out as there were no institutions of the Forest, Education and Engineering Departments to offer employment for successful students.

The Famine Commission have proposed an extensive scheme of agricultural instruction for Indian civilians at the expense of the Government, a cost that would be incurred, and, if such civilian a knowledge of the principles of agriculture, would provide bursaries to meet the entire requirements of the Madras Agricultural College, and secure to it a regular supply of at least 100 qualified students to its working charges; for, if it were that a course of lectures for a class of students is quite as costly as for a few or upwards. The benefit that would result from the general diffusion of knowledge amongst the rural class is well valued. If, as the Famine Commission say, a great benefit would result to the country if Land Revenue officers possessed a knowledge of the principles of agriculture, true, and, to a far greater extent, knowledge amongst the thesauries scattered over the country, with the agricultural classes of far more good in the present time than improvement.

Ordinary education, which is doing its beneficial influence in time, create inquiry, and efforts to improve matters will, no doubt, be made, but reform so urgently needed in this country, would not, in the next 100 years, and the far too urgent a nature of the year's delay. Seeing that though administered by the Government, it spends the one-ninth of the budget for promoting agriculture out of the Presidency, that the fact that native apathetic regarding titles, and the well-being of any decided compulsion made in native husbandry

placed within the reach of every class of it. The fact that the land pays four-fifths of the gross revenue of the Presidency, and that three-fourths of the population are employed in agriculture of the land, should never be lost in considering questions relating to the improvement of Madras agriculture.

It has already referred to the establishment of an Experimental Farm at Saidapet. The results, extracted from a report submitted by me, show the nature of the work in which the farm is engaged:—

It being the only one of the kind in South India, necessarily, been obliged to undertake the work in experimental agriculture, of a kind not undertaken by experimental farms in other countries.

From the almost entire absence of any written records of the country, the ignorance of the generally who are engaged in agricultural work, and the imperfect character of the records of previous efforts in improving native agriculture, was no choice but to institute on the farm a series of a very elementary character. It will be understood that experience gained in this way is but very slowly, as each result needs to be made under different conditions and circumstances, before any decided conclusions are possible. The institution to do the work of an acclimatization and agricultural society. It has been engaged in introducing new machines, implements, and tools of various kinds adapted to the requirements of Madras.

Attention has been given to subsoil drainage, methods of tillage, the restoration of exhausted soils, the introduction of irrigation water, the fertilisation of the soil by the use of lime, saltpetre, oil-cake, and other manures available in South India, the use of the ryot; the introduction of the most improved seeds to the climate of India, and adapted for the use of the country, such as *Sorghum saccharatum*, *Carolina paddy*, *Guinea fow*, *hargrasses*; New Orleans and other improved cotton; tobacco of all kinds; the production of a view to affording protection, shelter, and introduction of water-lifts, barn-machines, cultivators, reaping knives, &c., of improved tools, suited after undergoing modification for use in India; the improvement of native live stock by breeding and feeding, and by importing and breeding animals of good breeds for interbreeding stock."

Soil analyses, made shortly after the establishment, will give some idea of the nature of the soils at the time; the soils analysed are of the best on the farm:—

Elements.	No. 4 Field (east side)		No. 1 Field.

Total.....	99.400	99.809	100.000

The farm, being without natural pasturage of any value, it became necessary, soon after it was opened, to undertake experiments in producing fodder for the valuable stock it possessed. Attention was first given to the crops which, in Europe, furnish green fodder; but it was soon ascertained that, with the exception of Lucerne, they were ill-adapted for culture in the hot plains of South India. Most of the plants grew fairly well in the cold season, but died off immediately the hot weather set in. Amongst these crops were *Lolium perenne*, *Lolium Italicum*, *Trifolium incarnatum*, Lucerne, vetches, millet, and a great variety of pasture grasses. Seeds of grasses and fodder crops were also obtained from the United States, Mexico, New South Wales, Queensland, China, Egypt, Italy, &c. The prairie grass and buffalo grass of the United States, were quite unable to stand the great heat of Madras. Several varieties of native grasses from Queensland have thriven as well as could be desired, but they are far inferior to European grasses.

Guinea grass (*Panicum jumentorum*) has been thoroughly established, and now affords the chief pasturage at the farm. The cultivation of Guinea grass has been wisely extended. The grass is much coarser than any European pasture grass. All kinds of stock eat it freely, and thrive on it. When it was first introduced at the farm, it was grown as an irrigated crop. But it was thought, that if the habits of the plant could be altered, it might become adapted for cultivation on unirrigated land. Accordingly, several experiments were commenced with this view, the results of which have proved highly satisfactory. At the farm, at the present time, there are considerable areas of this crop, which, for at least three or four years, have depended entirely on the rainfall. This result has been obtained chiefly by inducing the plant to send its root deeper into the soil, and by gradually accustoming it to smaller and smaller applications of irrigation, water applied at gradually lengthening intervals, until finally discontinued. *Sorghum saccharatum* and *Sorghum Caffrorum*, imported from China, United States, and Australia have, through the farm, become thoroughly naturalised in Madras. When these valuable crops are more generally cultivated, there is every probability that the manufacture of Sorghum sugar will be largely engaged in. The experiments made at the farm show that both plants contain a large amount of sugar, that the saccharine juice is very easily extracted, and that the waste, after crushing, affords a very valuable cattle food. The Agricultural Department of Madras is using its best endeavours to extend the cultivation of these crops, chiefly in view to the provision of fodder for use in the hot dry season, when the natural pasturage is all burnt up. Crops of from 15,000 lbs. to 20,000 lbs. per acre of most excellent fodder have been raised on the poor soils of the farm, without the aid of irrigation, during growing periods, varying in length from eighty to one hundred and five days.

But by far the best results in growing fodder were obtained with the previously despised indigenous cereal crops of the country. Amongst these I may mention *Sorghum vulgare*, *Penicillaria spicata*, *Panicum Miliaceum*, *Panicum miliare*

*Panicum Italicum*, *Eleusine coracana*, and of the leguminous order, *Dolichos uniflorus*. Several of these crops, under very ordinary tillage, and without irrigation, have yielded crops of fodder of over 20,000 lbs. per acre, in periods of from seventy to one hundred days. With occasional irrigation *Sorghum vulgare* has, within twelve months, in several cuttings, yielded crops of fodder weighing upwards of 50,000 lbs. per acre, and in one experiment as much as 80,000 lbs. per acre was obtained, the plants standing generally over the ground about twelve feet high. The cost of producing fodder from these native plants is seldom higher than five shillings per ton, a price very considerably below its feeding value. The fodder is usually rich in saccharine matters, and very succulent and digestible.

Many experiments have been made with native grasses; the majority of them have been found to be very coarse, and almost worthless, excepting when very young. There is one grass, however, *Cynodon dactylon*, which gave very good results under high manuring and occasional irrigation. Further experiments are being made with native grasses, and with the grasses of other countries likely to thrive in South India. The discovery and extended cultivation of some really good grasses in South India would prove of immense advantage to the country.

Maize, introduced from America, Egypt, and North Australia, has thriven at the farm, and a large amount of seed has been distributed over South India.

Wheat of Northern India has been tried, but its cultivation has not yet proved a success, chiefly due to the great heat encountered at Madras. In some portions of the Presidency, at elevations of from 2,000 feet and upwards, wheat of fair quality may be produced, but, generally, the variety grown is inferior spelt variety.

Of fibre crops, many varieties have been introduced and cultivated at the farm. Of these, I may mention *Cannabis sativa*, *Corchorus capsularis*, *Crotalaria juncea*, *Linum usitatissimum*, *Bahmeria nivea*, and cotton of various kinds.

When the farm was instituted, it was believed generally that cotton could not be grown successfully on such light soils as those constituting the farm. However, it has been shown most conclusively there, that abundant crops of very fair cotton can be produced at a profit; while, over the Presidency generally, on soils far superior to those of the farm, the yield of clean lint is only, on the average, about 60 lbs. per acre; the average outcome per acre on the farm is fully three times this weight, while the price obtained is as high as for any cotton produced in South India. The farm has grown extensively Egyptian, New Orleans, Upland, Lea island, Yea valley, and other varieties, the seed of which has been distributed to native cultivators, and others. Many other kinds of crops have been experimented with; crops obtained from tropical countries abroad; crops introduced from the other provinces of India; and crops of South India not generally cultivated, or badly cultivated, apparently deserving of attention. But I cannot occupy your time in referring more fully to these crops. Those who are interested in the matter, and who wish for further information, will find full details in the annual

reports of the Madras Agricultural Department and in the "Saidapet Farm Manual," the compilation from these reports.

During the last ten years, many field experiments have been conducted at the farm, manures available in South India, but which recently, were almost unused in native husbandry. The results obtained with these manures have been widely published in the reports of the department and by other means. The experiments have shown that there is a great amount of valuable manure now wasted which the ryot could, with advantage, apply to his starved soil.

Seeing that South Indian agriculture is dependent on irrigation water, the proper use of this water has occupied a good deal of attention on the farm. It has been shown that good crops of paddy can be produced on sandy soils, with an expenditure of less than one-half the quantity generally required in native husbandry; results obtained by deep tillage and the use of organic manures. Experiments extended to unirrigated lands have shown that, with deep tillage and the use of vegetable manures, these soils are able to take up large quantities of moisture from the air during night, and to retain and store it practically securing irrigation from the sky in this direction, a great deal could be developed the drought resisting power of a large area of land in South India—a result of importance of which I need not occupy your time pointing out.

The heavy expense incurred by the farm in its primitive arrangement for raising water by wells, early attracted the attention of the engineering authorities of the farm, and many experiments were instituted with pumps and engines of different kinds, driven by steam-power, by cattle, and by manual labour. The use of the water-lifts, of the patterns most approved, have, for a long time, been worked on the farm, thus affording satisfaction to all persons interested in the matter every opportunity of judging for themselves the working of these machines. One of these water-lifts, which can be made up by almost any carpenter, raises the water at less than the cost at which it is raised by the primitive method generally used in South India. A new improved water-lift has been constructed from drawings, or models, supplied by the farm.

In my first paper (7th May, 1880) I pointed out very fully to the advantages the European plough possessed over the ploughs employed by native cultivators. The Saidapet farm has, for 12 years, been worked entirely by ploughs of modern make. They are each drawn by a single pair of cattle, and driven by a single ploughman. Ploughs have been imported from England, Sweden, and the United States. Light ploughs, made by Messrs. Howard of Bedford, and Messrs. Ransomes, Sims & Co. of Ipswich, have proved great successes. The ploughs now working on the Saidapet farm and that have been regularly worked the past 12 years, are still in a thorough order; of course, they have been kept in repair.

results of the experiments made at Saidapet show conclusively that it is a great mistake to recommend ryots to buy low-priced ploughs because they are low-priced. It is a far greater economy to pay £2 or £3 for a really well-ironed plough, than to pay 10s. or 15s. for a reconstructed plough, made of wood with working-parts, which is constantly needing repair—often when work is pressing—and seldom longer than two or three years. There are only many ryots who do not possess the means with which to buy a plough of the kind I recommend, but there are tens of thousands who do. It is as ridiculous to state that steam ploughs are used in England, because each farmer has the means to supply himself with such an implement, as to state that in India good ploughs of modern shape cannot be introduced, because the ryots are too poor to buy these ploughs.

Improvement of live stock has occupied much attention. There are no facilities at Saidapet for rearing a large breeding herd of cattle, but a number of bulls are kept there for improving the breed of the neighbourhood. A breed of cattle, introduced from Aden, has been introduced with a view to improvement.

The breed is noted as a dairy breed. It is found that, by the use of bulls of this breed, the producing capabilities of the cows of the indigenous breeds may be considerably improved. I mention that the average yield of milk of an ordinary native cow is less than two quarts per day, and you will understand what room there is for improvement, an improvement which would be of great benefit to the people generally, for nearly all are consumers of milk, if they could obtain it at a moderate price. Experiments made on the farm show that an average cow of Aden will yield daily at least six quarts of good milk. Experiments have also been made in determining the milking capabilities, under good management, of different native breeds, and of European breeds. The housing and management of horned stock have also attracted attention. How necessary this is, you will understand when I tell you that the cold which accompanied the cyclone that broke in the neighbourhood of Saidapet in 1877, killed, in the Revenue Division in which it is situated, 11,687 cattle, and 7,218 sheep, in a live stock numbering 30,000 head of cattle, and 16,000 sheep. On the farm, which was exposed to the effects of the cyclone, the loss was only three animals. Shelter in India is almost as necessary for stock as it is in England.

I could have liked to have described to you the actual work of the Madras Agricultural Department, but I have already trespassed on your time and attention. I must forbear. Before alluding to describe fully this and such indications of progress in agricultural reform as have been ascertained. Looking over a period of twelve years engaged in this enterprise, though I cannot point out any bright examples of progress, I feel satisfied that good has been done, chiefly in collecting and spreading information which, when the means for energetic work in agricultural education will bear fruit. Already, as I have pointed out, agricultural education, which would have been an impossible undertaking only a few years

ago, is now beginning its beneficial influences in the country; influences which, I firmly believe, will do for Indian agriculture what could be attained by no other means.

## MISCELLANEOUS.

### FAURE'S SECONDARY BATTERY.

Since the publication of Sir William Thomson's letter to the Editor of the *Times*, on the electric storage of energy (printed in the *Journal* of June 10, p. 622), Professor Osborne Reynolds, F.R.S., of Owens College, Manchester, has written the following letter to the *Times* :—

"Although agreeing with every word of Sir William Thomson's letter in the *Times* of to-day, and entirely sympathising with his enthusiasm as regards the marvellous box of electricity, still I feel that it would have been desirable if, in pointing out the importance of this new discovery, Sir William Thomson had guarded against a very probable misconception of the purport of his letter.

"The means of storing and re-storing mechanical energy form the aspiration, not only of Sir William, but of every educated mechanic. It is, however, a question of degree—of the amount of energy stored as compared with the weight of the reservoir, the standard of comparison being coal and corn. Looked at in this way, one cannot but ask whether, if this form of storage is to be the realisation of our aspirations, it is not completely disappointing. Large numbers are apt to create a wrong impression, until we inquire what is the unit. Eleven million foot pounds of energy is what is stored in 1 lb. of ordinary coal. So that in this box, weighing 75 lb., there was just as much energy as in 1½ oz. of coal, which might have been brought from Paris or anywhere else in a waistcoat pocket, or have been sent by letter.

"When we come to the question of the actual conveyance of energy for mechanical purposes, this view is of fundamental importance. The weight of the same amount of energy in the new form is 800 times greater than the equivalent amount of coal; and as a matter of economy, supposing that energy in this form might be had at a certain spot, and no capital were required for its conversion or storage, and that the energy were directly applicable, it could not be carried ten miles—that is to say, such energy cannot be economically useful ten miles from its source, although coal had to be carried 100 miles to the spot. This limit, in truth, falls far short of what has been already obtained by other means. By wire ropes, and by compressed air or steam, energy may be economically transmitted from 10 to 20 miles. So that if this is the utmost of what is to be done by means of the storage of electricity, this discovery adds another door to those which are hopelessly closed against the possibility of finding in Niagara or other water power a substitute for our coal, even when the object is motive power, and much more for that purpose for which five-sixths of our coal is used—the production of heat.

"It is very important that the people of this country should not shut their eyes to the fact that, so far from there being a greater prospect of the solution of the problem than when, about 20 years ago, Professor Jevons raised the alarm, the prospect is now much smaller. In the meantime, the capabilities of steel ropes, fluids in pipes, and electricity along conductors have been not only investigated, but practically tested and

found altogether wanting. And now it would seem that the storage of electricity must be added to the list."

Another letter on the same subject, from Professor W. E. Ayton, F.R.S., appeared in the *Times* on the next day, which is as follows:—

"Professor Osborne Reynolds's letter in your issue of Saturday, the 11th inst., shows that the first idea that has occurred to him on reading Sir William Thomson's letter on Faure's 'electric store' is, probably, what must have suggested itself to many engineers, viz., that so far from a million foot pounds being a surprisingly large amount of energy to be stored up in a mass of 75 lb., it is really extremely small; and, indeed, while crossing over from Paris at the commencement of last week, I could not help thinking that the passengers were bringing to England, literally in the carts and blacks on their coats, far more energy than had ever been imported into this country stored up in Faure's secondary batteries. But although it is perfectly true, as Professor Reynolds says, that 1½ oz. of coal contains about one million foot pounds of work stored up in it, this is by no means all that has to be taken into account in considering this question; for where is the engine for extracting this million foot pounds of work out of the 1½ oz. of coal? Indeed, as Professor Reynolds would himself tell us, we cannot get much more than one-tenth of this amount of work out of the 1½ oz. of coal, even in our largest steam-engines, which burn many pounds of coal per minute, and in which much heat has been wasted in getting up steam. And if we come to the burning of one single 1½ oz. of coal, I know of no engine that can obtain from this even one thousand foot pounds of work, or one-thousandth of the energy contained in the coal, if no other coal be used in getting up steam or in previously heating the engine.

"But if a secondary battery be allowed to drive a magneto-electro-motor or a dynamo-electric machine with separate exciter, only even for the short time necessary to develop, say, 30 foot pounds of mechanical work, I anticipate this can be done without using up in the whole process more than about 35 foot pounds of the electric energy stored up in the reservoir, since the experiments of Professor Perry and myself have shown that, when the motor is running at high speeds with a light load, as much as 93 per cent. of the electric energy put into a magneto-electro-motor is given out again as mechanical work measured by an absorption dynamometer.

"It may be answered, however, that if a small bit of coal, although containing a vast store of energy, is not of much practical use in producing work, in consequence of the absence, up to the present time, of a proper converter of the coal's energy into mechanical work, at any rate a small galvanic battery (a little Daniell's cell, for example) is not only a vast storehouse of power, but contains a store which we have the means of converting, without appreciable loss, into electric light or mechanical work. How, then, is a Faure's box a better store of electric energy than a little Daniell's cell? This question has precisely the same answer as, 'Why is a pinch of dry gunpowder better than a pinch of wet?' Not because the dry gunpowder has more energy in it than wet, but because the energy stored up in the dry gunpowder can be all, if we wish, used up quickly, and an explosion produced, whereas that in the wet can only be utilized bit by bit. So seven Faure's boxes will produce an illumination of 100 candles in Swan lamps for six hours, while seven Daniell's cells, or, indeed, twice that number, although possessing a store of power millions of times as great as that in the Faure's boxes, will not illuminate a single Swan light.

"But while fully recognizing the great advance made in the subject by Planté, and the recent improvements introduced by Faure, I do not wish to give the im-

pression that the problem is by any means solved, since, if the attempt that Mr. Perry no doubt like many other electricians, to convert at a low temperature the energy electric energy meets with even a fairly solution, then a fragment of coal, or, it may be of gas rich in carbon or carbonic oxide practical store of energy of incomparably more than any secondary battery."

Sir William Thomson, writing on the points out that the credit of first alluding to the natural and proper chief motor for the North American Continent, is due to Siemens, F.R.S., and adds, "that, under realisable conditions of intensity, a copper an inch diameter would suffice to take 3 power from water wheels driven by the (losing only 20 per cent. on the way) to 1 horse power at a distance of 300 British miles the prime cost of the copper amounting to less than £3 per horse power actually at distant station."

In a letter of the 11th inst., Sir W. writes further:—

"It will be seen that I thoroughly sympathize with Professor Osborne Reynolds in his aspirations for the utilization of Niagara as a motor, but the Siemens nor I agree with him in the case he asserts in his letter to you, published of to-day, that electricity has been tried wanting as a means for attaining such transmission of power, however, was not my letter to you published in the *Times* of and Professor Reynolds's disappointment in practical realization of electric storage, to not provide a method of portage superior through a wire, is like being disappointed in the invention of improvements in water-ways reservoirs, because the best that can be done of movable water-ways and fixed water-ways never let the water-carrier supersede water-ways over water-pipes can be laid.

"The 1½ oz. of coal cited by Professor Reynolds as containing a million of foot pounds in it, is no analogy to the Faure's accumulation of the same amount of energy. The accumulator is re-charged with energy when it is exhausted fresh store drawn upon when needed, and more than 10 or 15 per cent. with arrangement for practical purposes. If coal could be that is to say, if carbon could be extracted acid by any economic process of chemical action, as it is in nature by the growth of plants on sunlight for the requisite energy—the analogy to what is done in Faure's case is [In Sir William Thomson's letter, p. 68: "its own" should read "my own."]

#### THE CULTIVATION OF WHEAT-STRAW IN TUSCANY.

For centuries the manufacture of straw was a special art in Tuscany, and Siena, one of the most industrious of Tuscan towns, was for a long time the centre of the trade, which, however, was of importance and limited until the advent of the electric light, it commenced to attract considerable quantities of large quantities were manufactured both for exportation. There are three varieties of the golden plant (*glauca della Siena*) straw is called in Tuscany, the first is called *glauca senese*, which produces the best quality; the second, *Marzocco*, which is of a second quality; and the third, *Santa Flora*, which is of a third quality. The *Pantalone* is

mil, while the other two varieties require a more mil. Seed is sown in November and December, sowing to the season, the object being to have the straw up before the heavy frosts come, in the production of eleven hectolitres to each hectare, that is, 12½ bushels to the acre. It is sown as early as possible, in order that the growth of the straw may be so impoverished as to produce a stalk, at the same time having towards the end of the last knot the lightest and longest Side hills, with a gravelly soil, and high lands that have had a surface ploughing and harrowing, are specially adapted to the culture, low swampy grounds being generally, as dampness when the stalk is well grown the straw discoloured and coarse. The ground is ploughed and dug up in June, and left in this state until November, when the soil is again ploughed, and then it is ready for sowing. If the soil is rich and thin, a very light surface of manuring is usually used, but this is not frequently resorted to, in order to render the stalk thin and brittle. The straw is pulled out at the end of May or beginning of June: usually pulled out by hand by the roots when the stalk is half developed. For prooting the straw, a sunny weather is selected, as the rainy weather has an injurious effect upon it, often turning it when uprooted, the branches are tied together in sheaves, each sheaf, or "menata," is spread out in the sun of a fan to dry in the sun, from three days after which it is stowed away in barns, the straw being over, and the fields being only in the straw is again spread out to catch the summer dews, and to bleach in the sun for four weeks, but not the whole of the crop at the same time, in case of a sudden rain. During this process it is turned until all sides are equally white. The yellow colour of the straw was preferred, the extra white is more sought after. Before the straw is made up into braids, hats, and ornaments the straw has to be again bleached, fastened in bundles, and classified. It is then cut close above the joint from the top, and again tied up in bundles containing about sixty stalks in each. The small sheaves are then submerged in clear water for four or five minutes, and as soon as they become partially dried, are submitted to the burnt sulphur (in the proportions of one pound of sulphur to hundred bundles of straw) for three or four hours in rooms adapted for the purpose; during the process the doors of these rooms are left open. The classification of the straw is made according to length and the ear or end of the stalk having been previously cut. The straw below the first knot is used for forage or bedding, as it is worthless for the purpose of making braids or hats. There are no classes attending to her domestic duties, and at the same time making braids and sewing on hats. A female is found for their work at the nearest market, in many instances, special contracts are made with "fattores" (straw brokers) with the workmen directly, they supplying the straws into which the braids are made up. Many women make from 28 yards of braids a day, and some can finish 40 yards of common braids, but fine braids require very great care and cleanliness. Owing to the great strain upon the eyes, the finer kinds of straw can only be worked upon from two or three days a week; it takes, therefore, a woman from four to five days to make braid sufficient for the hats usually worn by men, while for the superior Leghorn hats for which requires from five to nine months for each hat. It is a noticeable fact that, in several districts where the straw is made, the workwomen suffer greatly from

affection of the eyes, caused by too close application to this kind of labour. Between 1822 and 1826, women employed in making braids realised from 6s. to 7s. a day, but at the present time the best braid-makers and hat-sewers only make about 1s. The most important centres of the straw industry are Brozzi, Signa, Prato, Fiesole, the Casentino, the Bolognese, and the Modenese. The province of Casentino is one of the most industrious in Tuscany, producing from 300,000 to 400,000 hats yearly, all for exportation. These hats, though hitherto comparatively unknown, are now very much sought after, on account of their strength and cheapness, prices varying from 4d. to 1s. each. In the Bolognese, the straw manufacture is confined chiefly to the mountain districts along the base of the Apennines, where the inhabitants of seventeen parishes are engaged in making the cheaper and coarser kinds. Laino and Searicalasino are the centre of this trade. Bolognese hats are brought to Florence to be fashioned, and the price paid is from 1s. 6d. to 2s. 6d. per dozen, and the quantity brought amounts to about 120,000 dozen yearly. For the last thirty years the annual exportation of straw goods from Tuscany averaged 12,000,000 lire, 5,000,000 lire alone being exported to the United States in 1878. By a comparison of the three principal products annually exported from Tuscany, straw goods show a value of 12,000,000 lire; silk, 5,000,000 lire, and timber, 4,000,000 lire.

#### UNITED STATES POST-OFFICE.

The United States Post-office Department has issued a statement of the results of an inquiry as to the amount and distribution of the postal business of the country during the year ending Dec. 31, 1880.

The whole number of letters posted was	1,053,252,876
"    "    " post-cards	324,556,440
"    "    " newspapers	812,032,000
"    "    " magazines and other periodicals	40,148,792
The whole number of packages of merchandise	21,515,832
Various	468,728,312
Total	2,720,234,252

The number of letters posted average twenty-one for each man, woman, and child in the United States. This total is then analysed, and the relative numbers of each State given in a table. The two extremes are, Alaska, with its unlettered population, and the district of Columbia, the centre of the postal system, and the seat of National Government. In Alaska, only one inhabitant in five is credited with one letter a year, while in the district of Columbia there are 85 letters posted for each inhabitant. The most letters are written where there is proportionally the largest intelligent adult population who are away from home, namely, the newer States and Territories. Colorado heads the list of letter-writing communities, with fifty-five and a fraction to each inhabitant. The settlers in Arizona write 32 letters each a year, Dakota 30, Montana 40, Nevada 32, California 26, Idaho 25, and Wyoming 42. The States, which supply most of the letter-writers of the Territories, in addition to being the great seats of manufactures and commerce, come next, New York, with 42 letters to each inhabitant, Massachusetts with 39, Connecticut with 38. The people of the South are not letter-writers generally, nor are they as much given to migration as the people of the north. The result is that the contributions of the Southern States to the mail bags are extremely small. The annual average for each inhabitant of Alabama is 7, Arkansas 8, Georgia 9, Kentucky 9, Mississippi 6, North Carolina 6, South Carolina 7, Tennessee 7, West Virginia 8. The figures for other Southern states are, it will be seen, somewhat

higher:—Florida 11, Virginia 11, Texas 12, Louisiana 15, New Mexico 13. The more Northern States which write the fewest letters are Delaware 16, Indiana 13, Wisconsin 17, Washington Territory 15.

### CINCHONA IN THE UNITED STATES.

Consul General Adams, of La Paz, Bolivia, states that he has no doubt but that the cinchona may be cultivated in some parts of the United States, where the soil and climate are favourable to its culture. After a full investigation into the cultivation of the *Cinchona calimaya* in Bolivia, he gives the following information to those wishing to make the experiment of growing the tree in the United States, which is taken from the *Oil and Drug News*:—"The seed is sown broadcast upon a hot-bed, such as gardeners prepare in the spring for their early vegetables. The manure of the llama, for which, in the United States, sheep manure might be substituted, is freely mixed with the surface soil of the hot bed, and, as the seed is very high, it should be slightly raked under, and the surface kept moist. As soon as the sprouts appear a shade should be constructed over the bed covered simply with leaves, straw or branches of trees, which, while it protects the tender plants from the hot sun, may allow the rain to penetrate and fall gently upon them, and it is advisable to locate such hot-beds on a hill-side, so that the water may quickly run off, continuous and limited moisture being required, rather than quantities of water and heavy falls of rain. As soon as the plant has grown to a height of from six to eight inches, it is ready for transplanting. The ground chosen for a quina plantation should also be sloping, if possible on the south side of hill or mountain, as experience has shown here that those located on level land do not prosper, and steep mountain sides are here preferred. The plants are set at regular intervals eight feet apart, and it is only necessary, if not better, to prepare the soil within a foot of where each plant is placed, as I am assured that by ploughing the whole field too much moisture would be retained in the soil. The plants are then slightly covered with fallen leaves or other rubbish to protect them from the hot sun a while longer, until they show a strong and healthy growth, after which all further care seems to be unnecessary, in Bolivia at least, where even the weeds are but superficially removed. A damp, warm climate, with heavy dews at night, and cloudy sky during the day, rather than a hot, burning sun—such as may be found in the mountainous regions of some of the Southern States, like Alabama and Georgia, where mists and threatening clouds hang over the mountains in summer and still no severe frosts occur in winter—this seems to be what is required for the cultivation of this plant: and I should not be surprised if the experiment should, under such conditions, prove successful, a result which would, undoubtedly, add greatly to the wealth and prosperity of the South. Bolivia being in the southern hemisphere, the seasons for sowing and transplanting in the United States will have to be changed: the former, instead of October here, should be done in April, and the latter in July, instead of January here. From these intervals it will be seen that the seeds require a long period to germinate and attain their first growth, but from all accounts, if the above directions are followed, and a little patience shown in the beginning, very little, if any, cultivation and trouble is necessary after the plant is transplanted and becomes firmly rooted and shows a healthy growth. In from five to six years the tree grows to a height of about 10 feet, and 5 to 6 inches in diameter, and at that age the bark contains the greatest per-centage of quinine, and is worth in Bolivia from 180 dollars to 200 dollars per quintal of 100 pounds. When the tree has attained this size and age, it is cut down close to the roots, the bark stripped

entirely from the trunk and branches, and on shoots from the root is allowed to grow into In India, I am told, the custom prevails to half of the tree, and allow this to grow again other half is taken off, but by this process, assured, the per-centage of the sulphate contained second growth is much smaller than that of the cinchona. Lately, since the cultivate tree has assumed such large proportions this seed has become an article of local commerce, should the experiments in the United States be successful, there would seem to be no difficulty obtaining the necessary seed in larger quantities.

### NOTES ON AMERICAN SCIENCE MECHANISM.

#### INCREASE OF IMMIGRATION.

At no time in the history of New York statistics of immigration furnished such figures as at present. During the week ending 28, the arrivals of immigrants were 20,178, Saturday of that week alone, the arrivals were 4,524, those of the day following being 4,524. Since the beginning of the present year, arrived, up to May 29, inclusive, no fewer than 1,000,000, when the returns of the 30th as added, and which will presumably be 8,000 an accurate idea of the influx of immigrants America through one port alone. The month of May alone exceeds the total number year 1878. The emigrants are despatched Western States after a very brief stay in

#### AN EXORATION INSPECTION BILL

The Assembly has passed the Emigration imposes a tax of a dollar a head on all entering the country by the port of New collected from the steam-ship companies them, and devoted to defraying the expenses the Commissioners of Emigration. It also to be inspected, so as to prevent fraud from exporting cripples, idiots, or other people.

#### AMERICAN CLAIMS FOR THE INVENTION LOCOMOTIVE.

In connection with the centennial of George Stephenson, certain Americans are against his being designated the "inventor" of the locomotive. This honour they claim for O. of Philadelphia, who, it is alleged, was the originator of the idea of a high-pressure engine, obtained a patent in 1786-7. Five years before went to Albany in the "Clermont," and years before Stephenson built the "Rocket" had in use a high-pressure engine, which motive and steam-boat in itself, as it was steam over the highway about a mile and a Schuylkill river, thence paddling its way wheel to Philadelphia. The construction of which was named "Erector Amphibolia," Americans conceived to warrant the title of the locomotive being associated with Evans rather than that of Stephenson, and genuine they quite admit, although only as a rather than a first inventor.

[Evans's carriage, like all the early locomotives a common road carriage. He is stated to have it in 1772. He was before Sydenham Murdock (1786), but later than Cugnot's steam-carriage in France in 1769. None of inventors can really claim to be the true locomotive. Trevithick made a true locomotive.

on rails, as well as a steam-carriage; the clock for some time on a circular tram near the site of Euston-square in 1808. It was Stephenson to have rendered the locomotive a practical thing. This is the credit which his true friends claim and this will not be lessened by any of the successful efforts of earlier inventors. No man has any knowledge of the early history of the thing would assign the merit of inventing the thing to George Stephenson.—*Ed. S. of A. J.*

#### INCREASING THE RAPIDITY OF LOCOMOTIVES.

American mechanic, Mr. Fontaine, is seeking to increase the rapidity of the locomotive by the application of a principle that a small wheel, when driven by a motor, makes more revolutions than the motor. With him it has not remained a mere conceit or it has passed into the experimental stage—having been constructed on this principle. We drew a train full of high officials over the Southern Railway, from Amberbury to St. Albans, a distance of 111 miles, in 98 minutes. That trip was considered satisfactory, is evident from the fact that the officials have given orders for engines to be constructed on the same model.

#### "HOLLAND HYDROGEN PROCESS" APPLIED TO THE STEAM-ENGINE.

Another improvement upon the steam-engine, having reference to the method of heating the water, is not effected by coals or coals as heretofore by hydrogen gas, which is generated as it is used. The principle of forming gas by the union of heated steam with an hydro-carbon has long been known, but by the method adopted by Dr. Charles of Chicago, and hence named the Holland process, it is stated that a greater degree of heat is resulted than by any other. This system of heat is applied to locomotives more than a year ago. It is only now that it has been improved in degree as to challenge public attention. By a brief account of an engine on the Flatbush and Atlantic Railroad, some idea will be had of the heating apparatus. The fire-chamber or (eight feet by three) is floored with iron plates, are screwed 362 burners, which project upwards two inches, each being enclosed by an open which acts like a lamp chimney to its flame. In number are also four strong iron retorts, which are set by iron pipes with the water tank of the engine oil tank on the tender, and the steam space boiler. When sufficiently heated, the retorts are heated steam and petroleum vapour together 52 burners, a certain number of which are under the boiler, and sustain their heat. From a carefully taken, the statistics of which have been furnished, are that it took seventy minutes to raise the pressure to ten pounds pressure, five and a-half gallons of oil being used in doing so. In fifteen minutes the pressure was doubled, at an expenditure of oil three-quarter gallons. After this the pressure was increased with great rapidity and at a greatly decreased cost of the oil, which is a very cheap product now. When the pressure reached about seventy pounds, it only required four minutes to raise it each day over this until it reached 120 pounds, the cost on each of these ten pounds being one cent.

The total time from lighting to the obtaining maximum pressure here mentioned (and after which the engine was despatched on its run) was two and a-half hours, twenty-six gallons of oil having been used. This oil, or naphtha, is a very cheap, the whole cost of the twenty-six gallons being only 75 cents, or 2s. 1½d. English.

When coal is employed to effect the same result a ton and a-half is said to be required, costing 10s. It is considered that, at a cost of 30 cents per hour, a fast train may be run. The

appearance of the flame is similar to that of pure hydrogen, that is, scarcely visible, although possessing great heating properties.

New York, June 1, 1881.

#### SWAN ELECTRIC LAMP AT PLEASLEY COLLIERY.

The Royal Commissioners upon Accidents in Mines, including Professor Abel, Mr. Warrington Smyth, Professor Tyndall, and others, made an examination last week of the experiments on the application of electric lighting to coal mines, which are being carried out at the Pleasley Colliery, near Mansfield. The pits are about 1,600 ft. deep, and the workings are very extensive, but in the present instance the light was applied to three workings only, situated at a distance of about one-third of a mile from the bottom of the pits. The Swan system was adopted, and the arrangements were carried out by Messrs. R. E. Crompton and Co. The lamps themselves were enclosed in lanterns of a very ingenious construction, designed and made by Messrs. Crompton, which enabled the very fragile glass bulbs to be carried about without fear of accident, and at the same time rendered it impossible that the fracture of the lamp within could cause an explosion, inasmuch as the air inside the lantern would suffice for the instantaneous combustion of the carbon filaments before the flame could be communicated to the external air. In working the coal, the men undercut the face to the depth of some five or six feet, and the superincumbent mass is then brought down by wedges or blasting. It is said that the new lamp was found to be admirably suited for the requirements of the workers, since it not only gave a light many times as intense as the lights it replaced, but it was equally brilliant in whatever position it was placed, and it required absolutely no attention. In addition to the lamps which were used in the actual workings of the pit, the pit bottom was lighted up with similar lamps. The number of lights employed was 94 in all, which were worked by the current of an ordinary Gramme machine driven by a portable engine placed near the top of the upcast shaft.

#### CORRESPONDENCE.

##### MANUFACTURES, TRADE, AND PROGRESS OF ENGLAND.

The important and opportune contribution of Mr. Hyde Clarke, in our last *Journal*, is of such vital importance to the glory, wealth, and progress of this country, and the working classes in particular, that I venture to supplement his statement by some facts that are within my own knowledge, that confirm fully the truth and wisdom of his remarks, which I consider should be received by all leaders of opinion as a warning that the time has arrived when some action should be taken to demand of the Government the appointment of a Minister to look after our commerce, both home, colonial, and foreign, and to prevent in time the ruin that the one-sided free trade, regulated as it is against our countrymen in every trade and calling, is fast bringing about.
